Promoting kidney health in people with type 2 diabetes: part 2

Fiona Murphy and Gobnait Byrne

ABSTRACT
The incidence of chronic kidney disease is increasing internationally with many risk factors for chronic kidney disease also being risk factors for type 2 diabetes. Nurses should use primary, secondary and tertiary prevention to minimise the incidence of chronic kidney disease when caring for individuals with type 2 diabetes. This article is the second in a two-part series on the interrelationship between these long-term conditions. Part 1 addressed the significance of using primary prevention to promote kidney health in adults living with type 2 diabetes; part 2 will discuss the use of secondary and tertiary prevention relevant to these long-term conditions.

Key words: Health promotion ■ Secondary prevention ■ Type 2 diabetes ■ Tertiary prevention ■ Chronic kidney disease ■ Cardiovascular disease ■ Nursing ■ Education ■ Screening ■ Self-management

This article will address the relevance of promoting kidney health using secondary and tertiary preventive measures. It will provide examples to assist nurses and other multidisciplinary team members who work in primary or community care or secondary or hospital care settings to promote kidney health with adults who have type 2 diabetes. It will continue to recognise the triple threat of chronic kidney disease (CKD), type 2 diabetes and cardiovascular disease (CVD) described in part 1 (Murphy and Byrne, 2023).

The Kidney Disease: Improving Global Outcomes (KDIGO) 2022 clinical practice guideline for diabetes management in CKD states that individuals should be managed using a comprehensive approach to maximise both kidney and cardiovascular (CV) outcomes. This should incorporate a combination of lifestyle modification and self-management along with first-line drug therapies depending on patients' clinical characteristics. Additional medications with established kidney and cardiac protection should be incorporated as determined by assessments of remaining risk, and further interventions provided as required to manage additional risk factors (Rossing et al, 2022).

Secondary prevention
Secondary prevention aims to minimise the effect of the disease by timely diagnosis using screening before any serious and long-lasting damage has occurred (Karunathilake and Ganegoda, 2018). The use of screening may be opportunistic or part of a planned national screening programme (George et al, 2022).

Screening for CKD in people with diabetes is usually sporadic in low- and middle-income countries. These countries are poorly equipped to manage diabetes-related CKD, particularly at advanced stages wherein kidney replacement therapy or conservative care may be needed (George et al, 2022).

A considerable amount of diabetes-related CKD can be averted through primary and secondary interventions targeted at disease management such as early referral to nephrology services for individuals with diabetes, which can reduce the rate of estimated glomerular filtration rate (eGFR) decline (George et al, 2022).

Screening
The most common causes of CKD are type 2 diabetes, hypertension and CVD; however, screening for lesser-known causes such as infections, genetic conditions and side-effects of drug therapy should also be conducted in individuals with CKD (Vanholder et al, 2021).

The ADA 2023 standards recommend that individuals with diabetes have regular screening for CKD, using eGFR and spot urinary albumin:creatinine ratio (ACR) at least annually from time of diagnosis. Screening of individuals with established diabetic kidney disease using spot urinary ACR and eGFR is recommended more frequently (1–4 times per year) depending on the stage of the disease (ElSayed et al, 2023a). The National
Institute for Health and Care Excellence (NICE) (2021) guideline on the assessment and management of CKD advocates that ACR monitoring should be individualised; for example, ACR may be monitored more regularly in adults with a high ACR (categories A2 or A3) and if a change in ACR is expected to lead to an adjustment in management.

The European Cardiovascular Society recommends that ‘ideally, all adults should be screened for the presence of hypertension, but most countries lack the required resources and infrastructure’ (Visseren et al, 2021: 3283). All individuals in Ireland who have a diagnosis of type 2 diabetes are screened by their GPs twice a year for hypertension (Health Service Executive, 2023). NICE (2022a) recommends at least yearly blood pressure measurements in adults with type 2 diabetes with no previous diagnosis of hypertension or kidney disease. The ADA Standards of Care in Diabetes–2023 recommend that blood pressure should be targeted at <130/80 mmHg in individuals with diabetes, hypertension and a low CV risk (ElSayed et al, 2023b). This blood pressure target is similarly advocated by the UK Kidney Association and should be aimed for to maximise CV outcomes (Fish et al, 2022).

To assist in early identification and minimisation of the risk of complications, nine key care processes should be completed as recommended by NICE (2023a) every 12 months in adults with type 2 diabetes. They include urine ACR, HbA1c, blood pressure, body mass index, serum creatinine and lipid measurements, foot surveillance, retinal screening and smoking status assessment. All involved, including service providers, health professionals, integrated care systems and adults with type 2 diabetes, must be made aware of these key care processes and ensure that systems – for example, laboratory provision for blood and urine tests and access to eye screening, foot protection and care services – are available. Primary and secondary care services, providers of diabetic eye screening, services for foot protection and community health services should also be available. When complications or changes in results are identified, this will require onward referral to an appropriate service (NICE, 2023a).

### Glycaemic control

Individuals living with diabetes need to maximise glucose control to decrease the risk or slow the progression of CKD and CVD (Hahr and Molitch, 2021; Rossing et al, 2022; ElSayed et al, 2023a). The Association of British Clinical Diabetologists and the Renal Association (ABCD-RA, 2021) alliance highlighted that there are difficulties with respect to increased risk of hypoglycaemia and dependability of HbA1c monitoring, which is necessary to accomplish intensive glycaemic control in individuals with moderate-to-advanced CKD. The ABCD-RA (2021) therefore provides glycaemic targets ranked by age, CKD stage and diabetic therapy with the aim of safely achieving tight glycaemic control targets in individuals with diabetic kidney disease. The UK Kidney Association has adapted these glycaemic recommendations (Herrington et al, 2021) (Table 1).

### Obesity

Screening by nurses using the Making Every Contact Count initiative for individuals who are overweight or obese would enable delivery of appropriate brief intervention to assist them to modify their lifestyles (Health Service Executive, 2016; Public Health England et al, 2016; Daly et al, 2019).

The prevalence of obesity is increasing globally and is a major contributory risk factor for type 2 diabetes, hypertension, CVD and, ultimately, CKD (Luyckx et al, 2020). Obesity is a risk factor for developing kidney stones and is also a major risk factor for developing pre-eclampsia (Mayrink et al, 2019). Pre-eclampsia is strongly associated with an increased risk of CKD during the 5 years after the woman’s last pregnancy (Kristensen et al, 2019), and gestational diabetes is independently associated with pre-eclampsia (Yang and Wu, 2022).

### Psychosocial health

There are many challenges for individuals living with the burden of CKD as they experience not only physical but also emotional and social difficulties, even if they do not yet require kidney replacement therapy, are receiving dialysis or have had a transplant. This can include doubts about their future, emotional stress, mental health concerns and various symptom burdens, along with the significant impact on quality of life for themselves, their families and care givers (Vanholder et al, 2021; 2023).

Kidney Care UK and the National Psychosocial Working Group (2022) recommend that the psychosocial care needs of every individual living with kidney disease should be assessed by renal specialists using validated processes. These should be conducted when individuals are first diagnosed, as treatment alters, as patients progress through the stages of CKD, throughout times of distress and during annual screening.

The same emotional challenges can affect those living with type 2 diabetes, which presents an abundance of extra tasks and

anxieties including those around dietary changes, medication burden and blood glucose monitoring. These can negatively influence overall diabetes management and increase risks of additional comorbidities.

High levels of stress influence individuals’ quality of life and that of their families and caregivers (Stewart, 2023). The ADA Standards of Care in Diabetes—2023 outline the concept of screening aimed at diabetes-associated concerns or worries. Following screening, nurses and other members of the multidisciplinary team can discuss any concerns raised by the individual and, with their permission, refer to suitably qualified psychosocial care practitioners for additional assessment and management; potentially, anxiety symptoms suggest there may be impediments to diabetes self-management behaviours or quality of life (Kidney Care UK and the National Psychosocial Working Group, 2022; ElSayed et al, 2023c).

Screening should be carried out periodically and when there is a change in disease, therapy or life situation (ElSayed et al, 2023c). The World Health Organization (Five) Well-being Index (WHO-5) measures general wellbeing (https://www.psykiatri-regionh.dk/who-5/who-5-questionnaires/Pages/default.aspx) and asks respondents to rate their interest, engagement and mood. Frequently used screening tools for anxiety and depression for people with type 2 diabetes include the Patient Health Questionnaire-9 and the Diabetes Distress Scale (Owens et al, 2019).

Individuals who have a fear of hypoglycaemia should obtain evidence-based interventions to assist them to improve recognition of hypoglycaemia symptoms and minimise their fear of same (ElSayed et al, 2023c). Fear of hypoglycaemia affects one in seven adults with diabetes in addition to their family members; people also fear diabetes-related complications as well as injections and needles (Hendrieckx et al, 2019). Adults with type 2 diabetes should actively participate in a person-centred approach to care for their psychosocial health and any difficulties that may arise (Hendrieckx et al, 2019).

Tertiary prevention
Tertiary prevention aims to reduce the effects of established disease (Naidoo and Wills, 2016). Diabetes self-management education and support (DSMES) programmes are a key component of tertiary prevention.

The consensus report on the management of hyperglycaemia in type 2 diabetes by the ADA and the EASD advocates that patients need to be encouraged to self-manage their condition to prevent the development of CVD and/or CKD and prevent other complications such as diabetic retinopathy; nephropathy and peripheral arterial disease (Davies et al, 2022). It is important that individuals with type 2 diabetes live well with their long-term condition through a shared decision-making approach and remain at the centre of any decisions concerning their care and management, with extensive support provided to empower them and their partners/family members/caregivers to self-manage their conditions (Murphy and Byrne, 2022a; 2022b).

NICE (2022b; 2023b) also recommends the use of a structured education programme for adults with type 2 diabetes (Table 2). DSMES programmes need to be evidence based and delivered by experts in diabetes care using a person-centred approach to enhance engagement in self-care activities. These programmes considerably enhance knowledge, glycaemic levels, clinical and emotional outcomes, and minimise hospital admissions and mortality as well as being cost-effective (Davies et al, 2022).

DSMES programmes should be provided on an ongoing basis. Every individual living with type 2 diabetes should be offered them when newly diagnosed, annually or when complications develop or when transitioning to insulin therapy. These programmes need to be flexible to meet individual cultural and literacy needs and should be delivered in a one-to-one or a group format (Davies et al, 2022).

To enhance quality of life and avoid complications, a decision cycle for person-centred glycaemic management in type 2 diabetes was devised by the ADA and the EASD. This involves the following key collaborative processes with the individual living with type 2 diabetes (Davies et al, 2018; 2022):

- Assessment of key individual characteristics, including the patient’s main concerns, prevailing lifestyles and health behaviours, comorbidities such as CKD, CVD or heart failure; clinical attributes, for example age, HbA1c and weight; and

Table 2. Examples of diabetes educational programmes
social determinants of health and matters, such as motivation, depression and cognition

- Consideration of specific aspects that influence choice of therapy: personalised glycaemic and weight goals, effect on weight, hypoglycaemia and cardiorenal fortification, fundamental physiological aspects, side-effect summaries of medication, intricacy of therapy (for example, how often an individual receives a treatment) or manner of administration, therapy choice to improve medication use and minimise discontinuation of therapy, and access to, price and accessibility of medication

- The use of shared decision-making to establish a management plan: encourage entry to DSMES programmes, include an educated and knowledgeable adult (such as a family member or caregiver) with the individual's consent, examine personalised preferences, note that language counts (incorporate person-first, strengths-based and empowering language), and use motivational interviewing, goal setting and shared decision-making

- Agreement on a management plan: identify SMART goals – specific, measurable, achievable, realistic and time limited

- Implementation of a management plan: assure there is a standard review; reviewing more frequently at the onset is usually beneficial for DSMES programmes

- Delivery of screening and continuing support for emotional wellbeing, lifestyle and health behaviours, acceptability of medications and biofeedback, comprising blood glucose monitoring/continuous glucose monitoring, weight, step count, HbA1c, blood pressure and lipid

- Appraisal and decision-making on a management plan: appraise a management plan, jointly agree on modifications, confirm agreed changes of treatment are instigated in a timely manner to avert therapeutic inactivity, assess decision cycle routinely (at a minimum of once or twice per year) and function in an integrated scheme of care (Davies et al, 2018; 2022).

The NHS diabetes programme accepts that face-to-face interventions do not always work for every adult and digital technologies afford novel opportunities to enhance an individual’s experience and outcomes and provide services in a more efficient manner, diminishing the burden on healthcare staff and the public. The digital workstream aims to ascertain the evidence base for innovative methods and encourage uptake (Phillips, 2021).

- Pharmacological therapies

When assessing or considering a change in therapy for adults with type 2 diabetes, the following should be discussed: how to enhance current therapy regimen taking on board issues such as the necessity to re-examine dietary and lifestyle advice; any adverse impacts of current therapy; adherence to current medications; prescribed dosages; and formulations. The discontinuation of medications that have had no effect on glycaemic control or weight unless there is a further clinical benefit for continuing therapy such as CV or renal protection should be considered, as well as whether swapping instead of adding medications might be effective (Nottingham Area Prescribing Committee, 2022).

A consensus report from the ADA and KDIGO on the Standards of Care in Diabetes – 2022 (de Boer et al, 2022) recommends pharmacological therapies targeted at preserving organ function and other therapies chosen to achieve intermediate goals regarding glycaemia, blood pressure and lipid. First-line medication therapy includes the use of renin-angiotensin system (RAS) inhibitors such as an angiotensin-converting enzyme inhibitor or an angiotensin-receptor blocker for people with type 2 diabetes who have hypertension and albuminuria (ACR ≥30 mg/mmol), which should be adjusted to the highest antihypertensive or maximum tolerated dosage. Multiple medications are often needed to regulate blood pressure, and a RAS inhibitor, dihydropyridine calcium channel blockers and diuretics can be combined to achieve personalised blood pressure targets (de Boer et al, 2022).

Advanced CKD is a risk factor for hypoglycaemia in type 2 diabetes and, where feasible, medications that control glycaemia without escalating the risk of this are selected. Metformin is recommended for individuals with type 2 diabetes, CKD and an eGFR ≥30 ml/min/1.73 m², with a lower dosage needed for individuals who are at elevated risk of lactic acidosis. Another first-line medication therapy is sodium glucose co-transporter-2 (SGLT-2) inhibitors with established kidney or CV benefit, which should be provided to individuals with type 2 diabetes and CKD (de Boer et al, 2022). The UK Kidney Association clinical practice guideline update on SGLT-2 inhibition in adults with kidney disease suggest it should be initiated in any of the four following clinical scenarios: eGFR of 20–45 ml/min/1.73 m²; eGFR of ≥45 ml/min/1.73 m² and a urinary ACR of ≥25 mg/mmol; symptomatic heart failure, irrespective of ejection fraction; and established coronary disease. This guideline proposes starting SGLT-2 inhibition to adjust CV risk and reduce the degree of kidney function decline in adults with an eGFR >45–60 ml/min/1.73 m² and a urinary ACR of <25 mg/mmol, while acknowledging impacts on glycaemic control will be limited. SGLT-2 inhibition should be considered for adults with an eGFR below 20 ml/min/1.73 m² to slow the advancement of kidney disease. A single-agent RAS inhibitor is recommended for use together with SGLT-2 inhibition where the RAS inhibitor is specified and tolerated. The use of SGLT-2 inhibition can be maintained until kidney replacement therapy is required (Herrington et al, 2023).

The use of a moderate statin is recommended for all individuals with type 2 diabetes and CKD for the primary prevention of CVD or a high-intensity statin for adults with known CVD and those with multiple CVD risk factors (de Boer et al, 2022). Additional risk-based therapies – alternatively known as second-line agents – include the use of a glucagon-
like peptide 1 (GLP-1) receptor agonist with established CV benefit approved for individuals with type 2 diabetes and CKD who do not meet their personalised glycaemic target with metformin and/or an SGLT-2 inhibitor or who cannot use these medications (Triozzi et al, 2021; de Boer et al, 2022).

A further recommended medication with established kidney and CV benefits is a nonsteroidal mineralocorticoid receptor antagonist (MRA) (finerenone) if urinary ACR ≥30 mg/mmol and potassium levels are normal (de Boer et al, 2022). A co-prescription of SGLT-2 inhibition can be considered with an MRA where each is individually indicated (Herrington et al, 2023).

Certain dipeptidyl peptidase 4 (DPP-4) inhibitors can be used where eGFR is <30 ml/min/1.73 m² and in haemodialysis or peritoneal dialysis for individuals who are not managed with GLP-1 receptor agonists.

The use of thiazolidinediones enhance insulin sensitivity, a frequent anomaly in advanced CKD, and maintains antihyperglycemic influences in these patients. Fluid retention and heart failure are concerns with low eGFR and cautious monitoring is needed. Insulin and short-acting sulfonylureas are usually required to regulate glucose when medications with less tendency to produce hypoglycaemia are contraindicated, not tolerated, unobtainable or inadequate (de Boer et al, 2022).

**Conclusion**

This article discussed the relevance of promoting kidney health in individuals living with type 2 diabetes using secondary and tertiary preventive measures. Nurses need to be aware of the major causes of CKD including diabetes, hypertension, CVD and obesity so should screen these individuals for the presence of CKD. They should use Making Every Contact Count to provide

Individuals with type 2 diabetes, cardiovascular disease and hypertension should be screened for chronic kidney disease. There are many emotional challenges from living with the burden of type 2 diabetes and chronic kidney disease; therefore, psychosocial screening and appropriate interventions are vital. Diabetes self-management programmes are a key component of tertiary prevention. Pharmacological therapies play a significant role in type 2 diabetes and chronic kidney disease management.
