Terms and Conditions of Use of Digitised Theses from Trinity College Library Dublin

Copyright statement

All material supplied by Trinity College Library is protected by copyright (under the Copyright and Related Rights Act, 2000 as amended) and other relevant Intellectual Property Rights. By accessing and using a Digitised Thesis from Trinity College Library you acknowledge that all Intellectual Property Rights in any Works supplied are the sole and exclusive property of the copyright and/or other IPR holder. Specific copyright holders may not be explicitly identified. Use of materials from other sources within a thesis should not be construed as a claim over them.

A non-exclusive, non-transferable licence is hereby granted to those using or reproducing, in whole or in part, the material for valid purposes, providing the copyright owners are acknowledged using the normal conventions. Where specific permission to use material is required, this is identified and such permission must be sought from the copyright holder or agency cited.

Liability statement

By using a Digitised Thesis, I accept that Trinity College Dublin bears no legal responsibility for the accuracy, legality or comprehensiveness of materials contained within the thesis, and that Trinity College Dublin accepts no liability for indirect, consequential, or incidental damages or losses arising from use of the thesis for whatever reason. Information located in a thesis may be subject to specific use constraints, details of which may not be explicitly described. It is the responsibility of potential and actual users to be aware of such constraints and to abide by them. By making use of material from a digitised thesis, you accept these copyright and disclaimer provisions. Where it is brought to the attention of Trinity College Library that there may be a breach of copyright or other restraint, it is the policy to withdraw or take down access to a thesis while the issue is being resolved.

Access Agreement

By using a Digitised Thesis from Trinity College Library you are bound by the following Terms & Conditions. Please read them carefully.

I have read and I understand the following statement: All material supplied via a Digitised Thesis from Trinity College Library is protected by copyright and other intellectual property rights, and duplication or sale of all or part of any of a thesis is not permitted, except that material may be duplicated by you for your research use or for educational purposes in electronic or print form providing the copyright owners are acknowledged using the normal conventions. You must obtain permission for any other use. Electronic or print copies may not be offered, whether for sale or otherwise to anyone. This copy has been supplied on the understanding that it is copyright material and that no quotation from the thesis may be published without proper acknowledgement.
Synthetic Routes Towards Guanidines of Biological Interest

A thesis presented to the University of Dublin
for the degree of Doctor of Philosophy

by

Julian W. Shaw, B. A. (Mod.)

Under the supervision of Prof. Isabel Rozas and Prof. David Grayson

School of Chemistry
Trinity College Dublin
August 2014
Declaration.

This work comprises a doctoral thesis submitted for the consideration of Trinity College Dublin.

I declare that this thesis has not been submitted as an exercise for a degree at this or any other university and it is entirely my own work, with due acknowledgement and reference given to the work of others, where appropriate.

I agree to deposit this thesis in the University's open access institutional repository or allow the library to do so on my behalf, subject to Irish Copyright Legislation and Trinity College Library conditions of use and acknowledgment.

Julian W. Shaw

August 2014

Trinity College Dublin
Acknowledgments.

I would like to sincerely thank Prof. Isabel Rozas and Prof. David Grayson. I could not have asked for more supportive supervisors. You were both a source of constant encouragement throughout my 4 years.

I was exceptionally fortunate to have worked in the Rozas group with some incredibly talented and fun loving people who made the lab a constantly enjoyable place to work. Without you guys (Daniel, Brendan, Elena, Paddy, Michela, Viola and Helen) my experience would not have been the same. I feel I should particularly acknowledge my part time flat mate Michela who put up with me when I was being insufferable and also calculated the $pK_i$ value of compound 406 in collaboration with Dr. Luis F. Callado at the Department of Pharmacology of the School of Medicine of the Basque Country University (EHT, Leioa, Spain). I would like to thank the Connon, Southern and Scanlan labs for constantly being helpful, all the technical staff (John, Manuel, Martin and Gary) and the administrative staff.

Outside of the lab I have a list of people who keep me constantly in good spirits and I truly could not have got through the past 8 years without you guys; Blaney, Carty, Dave, Graham, Mooney, Steve amongst a host of others.

I would like to thank the Irish Fulbright Commission who gave me the most incredible experience in the Scripps Research Institute, U.S.A. I am grateful to Prof. Phil Baran for his guidance and support during my time in La Jolla, to Ming Yan, an incredibly talented graduate student who I worked on the araiosamine project with and to everyone in the Baran lab who taught me so much. I would like to also thank the Nicolaou, Yu, Boger, Sharpless/Fokin and Shenvi labs for the use of their chemicals and equipment.

Finally, I can’t thank my parents and sister enough for always being there for me while I ‘mucked’ around in the lab for the past couple of years. Maybe someday I’ll get a ‘job’ ☹️.
Dedicated to my parents, Norman and Gladys.
Abstract.

The Rozas laboratory has been interested in the synthesis and biological evaluation of guanidine containing molecules for the past ten years. The application of guanidines as both minor groove binders (MGB) and $\alpha_2$-adrenoceptor ($\alpha_2$-AR) antagonists has been the focus of much of the research conducted. A number of promising results have been discovered in targeting the $\alpha_2$-AR, with a number of effective agonists and antagonists having been synthesised. $\alpha_2$-AR antagonists have proven to be a valid target for the alleviation of symptoms of Major Depressive Order. Historically these guanidines have been prepared by reacting the prerequisite anilines with $N,N$-bis-tert-butoxycarbonyl-thiourea in the presence of HgCl$_2$ to form the protected aryl guanidines. The use of mercury in such reactions is an obvious drawback and it was decided that its use should be eliminated from the synthesis of biologically active guanidines in Rozas group.

The overlying aim of this PhD project was therefore to design and implement the synthesis of guanidine containing compounds without the use of HgCl$_2$. As previously described in the literature there are a myriad of synthetic procedures available for such a synthetic endeavour. However, many of these procedures involve the use of either toxic reagents, economically expensive precursors or lengthy procedures.

The aim of this project was therefore to design syntheses that are environmentally friendly, atom economical, cost effective, scalable and simple to purify. Gratifyingly this project has resulted in the development of three new synthetic methodologies for the formation of guanidine containing molecules all of which adhere to the above stipulations. A synthetic route for the formation of spiro guanidine containing compounds was also developed as this structural motif is prevalent in natural product chemistry and potentially useful in medicinal chemistry. It is intended that this motif will be used to explore chemical space in the $\alpha_2$-AR. The new synthetic methodologies developed have proven useful in the Rozas group for the synthesis of new $\alpha_2$-AR antagonists.

Investigations into the synthesis of guanidine containing natural products were also conducted at the Scripps Research Institute, USA under the direction of Prof. Baran.

1. Introduction.

1.1. Guanidine.

Guanidine 1, with the molecular formula \( \text{CN}_3\text{H}_5 \) (Figure 1.1.1), is one of Nature’s most simple building blocks and is essential to all life.\(^1\) It forms the nitrogenous backbone of Guanine 2, one of the four main nucleobases found in the nucleic acids DNA and RNA\(^2\) and is also found in the ubiquitous amino acid arginine 3.\(^3\)

![Figure 1.1.1. Guanidine (1), guanine (2) and arginine (3).](image)

Guanidines ability to form hydrogen bonds (HBs) and its high basicity are two of its predominant characteristics. The high basicity of guanidine indicates that at physiological pH, guanidine will be protonated forming the guanidinium cation. The pK\(_{\text{aH}}\) of the guanidinium cation in water is 13.6.\(^4\) Due to the conjugation between the lone pair of the nitrogen atoms and the imine double bond, protonated guanidine has a number of resonance forms. These resonance forms delocalise the positive charge over the entire functional group leading to its high basicity (Figure 1.1.2). This feature of the guanidinium cation causes the nitrogenous backbone to be flat and this can often determine the conformation of substituted guanidinium species.\(^5\)\(^6\)

![Figure 1.1.2. Guanidinium resonance forms.](image)

In the guanidinium moiety there is six protons available for hydrogen bonding interactions, this allows the critical base pairing interactions possible for guanine (2) with cytosine in DNA\(^6\) and also facilitates numerous arginine (3) interactions throughout the mammalian body.\(^3\)\(^7\) Being protonated at physiological pH, the guanidine moiety in arginine (3) will be
cationic and planar. As well as being a HB donor, arginine is able to interact with other molecules through weaker interactions such as π cation interactions. The guanidinium cation has 6π electrons and all of them are in the bonding orbitals (Figure 1.1.3).

![Diagram of electronic configuration](image)

**Figure 1.1.3.** Electronic configuration (Hückel molecular orbitals) of guanidinium cation and guanidine. (DE: delocalisation energy).

This gives guanidinium a type of Y aromaticity, allowing interactions with planar electron rich moieties such as phenyl rings. These properties of guanidine make it an important functional group in both the biological and chemical sciences.

### 1.2. Pharmaceuticals containing guanidines.

The ever pressing need for novel pharmaceuticals drives chemical research forward, developing new ideas and strategies which ideally will find commercial application. One could therefore surmise that the level of importance of either a moiety or functionality in organic chemistry is related to its prevalence in the pharmaceutical industry. The abundant nature of the guanidine in pharmaceuticals therefore is an indicator of its status as a chemical entity.
1.2.1. Zanamivir.

Zanamivir (4, trade name Relenza) is a commercially available guanidine containing pharmaceutical used in the treatment of infection caused by the influenza A and influenza B virus. It is a neuraminidase inhibitor (NI) and was the first one to reach the market closely followed by oseltamivir. Neuraminidase enzymatic activity is essential for the release of recently formed virus particles from infected cells and is thus required for the influenza virus to spread in the body. Inhibition of this pathway is therefore a viable target for antiviral therapy. Global sales of zanamivir reached a high of €910 million in 2009 when governments stockpiled the drug due to the predicted outbreak of influenza virus A H1N1 (swine flu). Zanamivir was initially synthesised by a late stage guanidylation reaction. Primary amine 5 was reacted with formamidine sulfonic acid 6 to generate the desired guanidylated compound (Scheme 1.2.1.1).

![Scheme 1.2.1.1.](image)

1.2.2. Cimetidine.

Cimetidine (7, trade name Tagamet) is a guanidine pharmaceutical of exceptional importance. Developed in 1976, it was one of the first drugs to be designed rationally as a histamine H2 receptor competitive antagonist to inhibit stomach acid production. Its significance as a rationally designed drug is due to its stepwise development. Cimetidine was developed using histidine, the natural agonist, as a lead compound. Its primary uses are in the treatment of heartburn and peptic ulcers. It was also the first drug to break annual sales of $1 billion in 1986, making it the first blockbuster drug. Cimetidine antagonism suppresses the normal secretion of acid from the parietal cells. The guanidine functionality is introduced in this compound by initial reaction of amine 8 with 9, which is subsequently exposed to
methylamine to generate the substituted guanidine moiety found in cimetidine (Scheme 1.2.2.1).\textsuperscript{16}

\textbf{Scheme 1.2.2.1.}

1.2.3. Clonidine.

Clonidine (10, trade name Catapres) is an $\alpha_2$-adrenoceptor agonist used in the treatment of high blood pressure, pain, anxiety and panic disorder.\textsuperscript{17} It agonises $\alpha_2$-adrenoceptors causing a decrease in the release of noradrenaline (NA) from presynaptic neurons. Clonidine is considered as a non-specific drug acting on a number of different pathways resulting in a number of undesired side effects. Such side effects can include dizziness, orthostatic hypotension (a drop in blood pressure that occurs upon standing) and anxiety. The cyclic guanidine moiety is formed through reaction of thiourea derivative 11 with ethylenediamine to yield the desired functionality (Scheme 1.2.3.1).\textsuperscript{18}

\textbf{Scheme 1.2.3.1.}

1.2.4. Iobenguane.

Iobenguane (12, trade name Adreview) also known as meta-iodobenzylguanidine (mIBG) is a radiopharmaceutical.\textsuperscript{19} There are two forms of 12, one containing the radioisotope iodine-123 ($t_{1/2} = 8$ hr) and the other containing iodine-131 and both can be used in the imaging of cancerous tumours.\textsuperscript{20} Due to the structural similarities of 12 to noradrenaline (NA) it localises in adrenergic tissue and is therefore very useful in the identification of tumours such as phaeochromocytomas (a neuroendocrine tumour of the medulla of the adrenal glands) and
neuroblastomas (a malignant tumour that develops from tissue). In order to prevent problems arising from the uptake of radiolabelled iodine in the thyroid potassium iodide is taken in conjunction with 12. This inhibits the uptake of any radiolabelled iodine which could potentially cause thyroid carcinogenesis. Compound 12 is synthesised by reacting iodo benzylamine 13 with cyanamide to generate 14 which can then undergo substitution of iodine with radiolabelled 123I (Scheme 1.2.4.1).

Scheme 1.2.4.1.

1.2.5. Desmopressin.

Desmopressin (15, trade name DDAVP, Figure 1.2.5.1) is an arginine containing pharmaceutical. It is a synthetic analogue of vasopressin which is a neurohypophysial hormone associated with the reduction of urine production. Desmopressin is most often used in the treatment of diabetes insipidus (a condition involving the excretion of severely diluted urine) and bedwetting. Desmopressin exerts its mode of action by binding to V2 receptors in renal collecting ducts and increases the reabsorption of water, controlling the amount of water that is being excreted as urine.

Figure 1.2.5.1. Structure of Desmopressin.
1.2.6. Gleevec.

Gleevec (16, trade name Imanitib, Figure 1.2.6.1) although not a guanidine containing pharmaceutical, is of particular interest for this thesis due to the presence of the 2-aminopyrimidine moiety which structurally is similar to guanidine. The aromaticity of the pyrimidine ring causes the typical characteristics of the guanidine portion to be lost. 2-Aminopyrimidine can therefore be thought of as a ‘masked’ guanidine. Gleevec is a tyrosine kinase inhibitor used as a chemotherapeutic against a wide variety of cancers that was rationally designed from N-phenyl-2-aminopyrimidine. Gleevec works by preventing a tyrosine kinase enzyme from phosphorylating subsequent proteins and initiating the signalling pathway that is necessary for cancer cell development. This interaction therefore prevents cancer cell growth leading to their death.27-29 Gleevec is a blockbuster drug with annual sales of $4.7 billion. As a chemotherapeutic it is one of the most expensive options available to patients with a yearlong course in the USA costing €68,000 in 2012.30

![Figure 1.2.6.1. Structure of Gleevec.](image)

1.3. Guanidine natural products.

The symbiotic nature of natural product chemistry and the pharmaceutical industry has been known for years.11,12 The earliest medicines were derived from substances found in nature and numerous new pharmaceuticals have stemmed from natural products. The renaissance in natural product chemistry is evident in the state of the art syntheses recently published by Baran and co-workers at the Scripps Research Institute, La Jolla, CA.31,32 Oubagenin33 17 and Ingenol34 18, shown in Figure 1.3.1, are biologically active compounds of significant interest and previously were thought to be too complicated for efficient laboratory synthesis; now they have been prepared in ways which make them feasible for large scale production.
Figure 1.3.1. Biologically active natural products oubagenin 17 and ingenol 18.

As in the synthetic pharmaceutics, guanidines are prevalent in natural product chemistry and a number of these natural products have interesting biological activities.\textsuperscript{35} Both in terrestrial and marine sources guanidine natural products are abundant. In particular, cyclic guanidines and aminoimidazole natural products are continuously being discovered often with interesting properties.\textsuperscript{36}

Figure 1.3.2. Natural products zetekitoxin 20, palau’amine 21, saxitoxin 22 and dibromophakellin 23 all contain the cyclic guanidine aminal 19.

A motif that appears in a wide variety of guanidine natural products is bicyclic guanidine aminal 19 (Figure 1.3.2).\textsuperscript{37} This cyclic structure is central to a number of natural products
such as zetekitoxin 20, palau’amine 21, saxitoxin 22 and dibromophakellin 23 shown in Figure 1.3.2. Although many of these natural products have been extensively investigated in terms of their preparation, there has been no report of divergent syntheses stemming from the core 19. The synthesis of this heterocyclic core as a means of exploring biological activity associated with a number of these compounds would be of great interest.

Saxitoxin 22, a naturally occurring guanidinium toxin first isolated as a paralysing shellfish poison, is a potent, selective and reversible inhibitor of voltage gated sodium ion channels. In electrically excitable cells these channels are responsible for the rising phase of the action potential. Molecules that interact specifically with these ion channels are sought after in a desire to further understand how these channels affect electrical signals in neuronal cells. Aberrant behaviour of voltage gated sodium ion channels is thought to be associated with a number of diseases such as arrhythmia, epilepsy, neuropathic pain and congenital analgesia.

A number of natural products from the pyrrole-imidazole family have shown to have potent biological activity. Of particular interest is dibromophakellin 23 which has been shown to act as an $\alpha_{2B}$-adrenoceptor agonist. Non selective agonists of the $\alpha_2$-adrenoceptor GPCRs have been used clinically in antihypertensive treatment, pain control and as anaesthetic adjuncts. However, these non-specific agents have a number of side effects which is thought could be prevented by means of selective agonism of specific $\alpha_2$-adrenoceptor subtypes. Facile access to the core 19 would allow its derivatives to be synthesised in a convergent manner allowing for investigations into which regions of 23 determine its specificity for $\alpha_{2B}$-ARs.

Other biologically interesting guanidine natural products include the batzelladine family (Figure 1.3.3), which have shown activity against specific human cancer cell lines and malaria protozoa and the streptothricin family of antibiotics which are known to have antibacterial activity against Escherichia coli, Bacillus subtilis and Staphylococcus aureus amongst many others.
Figure 1.3.3. Structure of compounds 24 and 25 which are biologically active guanidine natural products.

1.4. Applications of guanidines in Organic Chemistry.

As alluded to previously the specific characteristics of guanidines determine their biological activity. These characteristics, namely high basicity, planarity and hydrogen bonding ability, can be harnessed in organic chemistry to facilitate chemical transformations. A particular niche for guanidines has been uncovered particularly in the field of organocatalysis which has undergone a renaissance in recent times. The facile synthesis of guanidines would therefore facilitate their use in organic chemistry.

1.4.1. Guanidines as Brønsted Bases.

One of the most fundamental characteristic properties of guanidines is their high basicity. This allows a myriad of organic transformations to be facilitated, often when the use of other inorganic bases of similar pKₐ values is undesirable. Often basic guanidine catalysts can have a dual method of activation. Firstly, neutral guanidines (such as 26) can deprotonate a substrate A-H (Figure 1.4.1.1), forming a guanidinium cation 27.
This species can then act as a HB donor to attract another molecule such as B. Structures A and B are now ideally positioned for an enantioselective interaction due to the chiral environment that they are locked into. Reaction and subsequent protonation results in regeneration of the guanidine catalyst 26 and formation of a new product, in this case AB-H.

1.4.1.1. Strecker Reaction.

One of the earliest examples of guanidine catalysed enantioselective reactions came from the laboratory of E. J. Corey at Harvard University with the use of catalyst 30 (Figure 1.4.1.1.1).  \(^{55,56}\)
The guanidine catalyst 30 is able to facilitate an enantioselective reaction by firstly deprotonating HCN and holding the cyano anion in place while the guanidinium cation can now form a HB with the imine 31 and allow attack by cyanide from only one face leading to an enantioselective reaction (Scheme 1.4.1.1.1). The phenyl ring of the guanidine catalyst also would be perfectly positioned to assist in holding the imine molecule in the correct orientation through π–stacking interactions. This reaction between aromatic imines and hydrogen cyanide in the presence of this guanidine catalyst led to (R)-α-amino nitriles 32.

Scheme 1.4.1.1.1.

Interestingly when aliphatic imine 33 was used instead of aromatic imine 31 an inversion of product configuration was observed with (S)-α-amino nitriles being the stereochemical outcome (Scheme 1.4.1.1.2). This observation is believed to stem from either steric repulsion for aliphatic substrates or attractive interactions for aromatic substrates.

Scheme 1.4.1.1.2.
An analogous racemic reaction with either aldehydes or ketones replacing imine has been investigated by Feng and coworkers. The use of 1,1,3,3-tetramethylguanidine (TMG, $pK_a = 23.7$) to activate TMSCN was employed under solvent free conditions. TMG could be converted to a reactive guanidinium cation upon exposure to TMSCN as proven by X-ray crystal structure analysis. This intermediate acts as a catalyst readily reacting with both aldehydes and ketones through a six membered transition state. Then, the corresponding cyanohydrins are generated and the catalyst regenerated.

\end{align*}
\]

**Figure 1.4.1.1.2.** TMG catalysed Strecker reaction.

1.4.1.2. **Michael Reaction.**

The Michael reaction (1,4 conjugate addition) is one of the most utilised and important reactions in organic chemistry to generate either new C-C or C-X bonds. The need for
enantioselective variations is therefore essential. A plethora of examples using guanidine catalysed Michael reactions has arisen over the past years.\(^6\) In one of the earliest examples guanidine catalysts were shown to be effective in the Michael addition of either 1,3-diketones or malonates to cyclic enones in very good yields and stereoselectivities. In the example shown in Scheme 1.4.1.2.1, 2-cyclopenten-1-one \(^39\) was reacted with dimethyl malonate \(^40\) at room temperature for 5 days in the presence of catalyst \(^41\) leading to 92% yield of the desired product \(^42\) with 78% ee.\(^6\)

\begin{align*}
\text{Scheme 1.4.1.2.1.} \\
\begin{minipage}[c]{0.5\textwidth}
\begin{center}
\includegraphics[width=\textwidth]{scheme1.png}
\end{center}
\end{minipage}
\begin{minipage}[c]{0.5\textwidth}
\begin{align*}

&92\%, 78\% \text{ ee}
\end{align*}
\end{minipage}
\end{align*}

Another interesting example of the use of catalyst \(^41\) in Michael additions is the enantioselective tandem alkyne-allene isomerization and resulting 1,4-addition of derivatised aniline amides \(^43\) to form axially chiral lactams \(^44\) (Scheme 1.4.1.2.2).\(^6\)

\begin{align*}
\text{Scheme 1.4.1.2.2.} \\
\begin{minipage}[c]{0.5\textwidth}
\begin{center}
\includegraphics[width=\textwidth]{scheme2.png}
\end{center}
\end{minipage}
\begin{minipage}[c]{0.5\textwidth}
\begin{align*}
\text{43} &\xrightarrow{\text{41 (10 mol\%) THF, rt, 72 h}}} \text{44} \\
&67\%, 89\% \text{ ee}
\end{align*}
\end{minipage}
\end{align*}

This reaction proceeds with good yield and very good enantioselectivity. Again the dual method of activation of the guanidine catalyst is shown with first deprotonation of the acidic proton \(\alpha\) to the ester forming the allene \(^45\) and subsequent ring closure arising from a 1,4-
addition by the nitrogen of the amide onto the electrophilic central conjugated carbon atom of the allene.

A wide variety of guanidine catalysts have shown to be effective for enantioselective Michael reactions. The cutting edge of this chemistry can be observed in a recent publication from the laboratory of Zhao at the University of Texas, San Antonio, dealing with guanidine catalysed tandem Henry-Michael reaction between 7-oxo-hept-5-enals and nitromethane to generate trisubstituted cyclohexanols in a highly enantioselective manner (Scheme 1.4.1.2.3).

This reaction proceeds by guanidine catalysed addition of nitromethane to the aldehyde as is well known in the chemical literature, the resulting nitro alcohol then presumably undergoes deprotonation and subsequent 1,4-addition to the enone moiety in a stereospecific manner to generate the desired highly substituted cyclohexanol products (Scheme 1.4.1.2.4).
An application of the guanidine catalysed Michael addition has been used in the synthesis of huperzine A 49, a candidate drug for the treatment of Alzheimer’s disease (Scheme 1.4.1.2.5). Interestingly, the authors report that, while several other routes were examined for installation of the unsaturated carbon bridge, only TMG catalysed Michael addition between enol 50 and α,β unsaturated aldehyde 51 was successful to afford compound 52.

**Scheme 1.4.1.2.5.**

The mechanism of this reaction presumably follows a Robinson type annulation pathway to efficiently form the bicyclic system.

**1.4.1.3. Aza-Michael Reaction.**

The need for enantioselective carbon nitrogen bond forming reactions is evident from the ubiquitous nature of highly nitrogenated compounds throughout the pharmaceutical industry and thus, aza-Michael reactions offer an appealing method for the generation of C-N bonds. A number of guanidine catalysed enantioselective aza-Michael reactions have been investigated recently in the literature. One example from Nagasawa and coworkers shows that guanidine catalyst 53 can effectively catalyse the addition of pyrolidine to α,β-unsaturated lactones, however, no enantioselectivity was achieved (Scheme 1.4.1.3.1).

**Scheme 1.4.1.3.1.**
1.4.1.4. Oxa-Michael.

Oxa-Michael reactions have proven useful in the synthesis of C-O bonds when employing oxygen derivatives as a nucleophile. Ishikawa and co-workers have recently used such a method generating a highly substituted chromane skeleton 54 through a guanidine catalysed intramolecular oxa-Michael reaction.\textsuperscript{72} A number of bases were investigated to coax the ring closure of 55, however, only TMG proved effective and could be used in catalytic quantities (Scheme 1.4.1.4.1).

\begin{center}
\textbf{Scheme 1.4.1.4.1.}
\end{center}

\includegraphics[width=0.8\textwidth]{scheme14141.png}

An enantioselective variation of this 6-exo-trig-type cyclisation was found to be useful for the synthesis of vitamin E and its derivatives.\textsuperscript{72} In a related ring closure, quinine had been employed as an organocatalyst to facilitate the reaction occurring enantioselectively,\textsuperscript{74} however, in this instance quinine had no effect and it was realised that other amine bases would need to be examined.

After extensive investigation into varying guanidine organocatalysts it was discovered that the use of catalyst 56 was able to promote the ring closure with very good yield and moderate enantioselectivity (Scheme 1.4.1.4.2).
The geometry of the olefin also played a crucial role in the outcome of the reaction with significantly higher yields and ee values being obtained when the E isomer was used. The origin of the asymmetric induction in this reaction is shown in Figure 1.4.1.4.1. The presence of the hydroxyl moiety on the catalyst was shown to be crucial in the efficacy of the reaction.

Figure 1.4.1.4.1. Pre-transition state 58 assembly of substrate 55 with catalyst 56.72

1.4.1.5. Aldol Reaction.

A guanidine 46 catalysed enantioselective example of the venerable aldol reaction has been published in the Journal of the American Chemical Society in 2010 by Misaki and co-workers.73 This particular example involves the reaction of 5H-oxazol-4-ones 59 with a number of varying aldehydes 60 to generate chiral α,β-dihydroxycarboxylic acid precursors 61 and their derivatives 62 (Scheme 1.4.1.5.1). The introduction of quaternary chiral centres at the α-carbon atom of carboxylic derivatives results in important chiral precursors such as
compounds 62 and it is also useful in the preparation of many biologically active natural
products.\textsuperscript{74}

Scheme 1.4.1.5.1.

\[
\begin{align*}
\text{CF}_3 & \quad \text{CF}_3 \\
\text{OH} & \quad \text{CF}_3 \\
46 & \\
\end{align*}
\]

1. 53 (5 mol\%) \text{THF, 0 °C}
2. \text{DMAP, Ac}_2\text{O, NEt}_3

The particular guanidine catalysts used in this study (for example compound 46) were
designed to carry a hydroxy group adjacent to the guanidine functionality. It was hoped that
this would enable hydrogen bonding and subsequent activation on the aldehyde in a defined
stereochemical environment. Additionally, it was assumed that the anionic enolates would
have their geometry determined by the guanidinium cation, positioning them in a reactive
location adjacent to the aldehyde as depicted in Figure 1.4.1.5.1.\textsuperscript{73}

The products of this reaction gave primarily \textit{syn} diastereomers in excellent enantiomeric
excess and in moderate to excellent yield. This is an inspiring example of the dual modes of
activation of guanidine organocatalysts.
1.4.1.6. Mannich Reaction.

The enantioselective Mannich reaction is a powerful method in the synthesis of chiral β-aminocarbonyl compounds. The ability of this C-C bond forming reaction to access α,β-diamino ester 63 was utilised by Kobayashi et al. Fluorenone imines of glycinate 64 were found to be more reactive than benzophenone imine derivatives when reacted with N-Boc protected imines 65 under these guanidine catalysed conditions (Scheme 1.4.1.6.1). This is thought to arise from the resonance stabilisation of the α-anion involving the 14 π-electrons of the aromatic anionic fluorene system. The diamino products were produced in excellent yield, enantioselectivity (ee) and good to excellent syn:anti selectivity.

Scheme 1.4.1.6.1.

Nagasawa and co-workers have also developed guanidine catalysed enantioselective Mannich reaction between malonate derivatives and N-Boc protected imines.

1.4.1.7. Aziridination of aldehydes.

An interesting use of guanidine 67 is in the aziridination of aldehydes 68 facilitated by the use of TMG as a base (Scheme 1.4.1.7.1).
Chapter 1

Introduction

Scheme 1.4.1.7.1.

Formation of a guanidine ylide followed by addition to an aldehyde forms a mixture of open ring 69 and closed ring 70 products in equilibrium (Scheme 1.4.1.7.2). Subsequent exposure to \( \text{Ac}_2\text{O} \) facilitates the formation of the desired aziridine 71 in good to excellent yields with good stereochemical control. Urea 72 is formed as a side product.

Scheme 1.4.1.7.2.

1.4.2. The uses of guanidines as weak Bronsted acids.

1.4.2.1. Claisen Rearrangement.

The [3+3]-sigmatropic rearrangement of allyl vinyl ethers (Claisen rearrangement) has effectively been used for over 100 years in the formation of C–C bonds. Enantioselective variations have received extensive attention in recent years and Jacobsen et al. have utilised guanidine organocatalysis in their synthesis of \( \beta \)-keto ester Claisen products 73. Initial investigations into both urea and thiourea catalysed Claisen rearrangements indicated that neither induced a rate enhancement in the reaction. However, preliminary investigations into
guanidinium catalysis proved fruitful and, thus, chiral guanidinium catalyst 74 (Scheme 1.4.2.1.1) was designed to effect Claisen rearrangement of substrates 75.

Scheme 1.4.2.1.1.

1.4.2.2. Henry Reaction.

The reaction between a nitroalkane and either an aldehyde or ketone in the presence of a base is a classic C–C bond forming process known as the Henry reaction (or nitro aldol reaction) and was discovered by L. Henry in 1895. The synthetic utility of this reaction stems from the plethora of transformations available to the β-nitro alcohol products formed (Figure 1.4.2.2.1).

Figure 1.4.2.2.1. Synthetic versatility of the Henry reaction.

Therefore, the high basicity of guanidines and their hydrogen bonding abilities make them excellent candidates as catalysts of the Henry reaction. Pioneering work from the laboratory
of Nagasawa utilised guanidine catalysis to provide nitro aldol products 76 in a highly \textit{syn} selective manner in high yield and \textit{ee} (Scheme 1.4.2.2.1) from aldehydes 77 and nitroalkanes 78.

\textbf{Scheme 1.4.2.2.1.}

![Scheme 1.4.2.2.1.](image)

Ensuing analogous studies using the opposite enantiomer of catalyst 79 with nitromethane as the nitroalkane source led to excellent \textit{anti} selectivity proving the synthetic utility of this catalytic system. The hydrogen bonding abilities of this catalyst are essential as shown in the authors working model for conformational ordering (Figure 1.4.2.2.2).

\textbf{Figure 1.4.2.2.2.} Hydrogen bonding interactions of catalyst 79 in enantioselective Henry reaction.

The use of guanidine catalysis has also shown to be of use in non enantioselective Henry reactions.
1.4.3. The use of guanidines in Lewis base catalysis.

1.4.3.1. Aldol Reaction.

The dual mode of activation of guanidine organocatalysts can be particularly effective in the case of intramolecular aldol reactions. Baati and co-workers have demonstrated how 1,5,7-triazabicyclo[4.4.0]dec-5-ene (TBD, 80) can induce the formation of 2-ketocyclopentanols 81 from the corresponding ketoaldehydes 82 (Scheme 1.4.3.1.1). 84

**Scheme 1.4.3.1.1.**

Nucleophilic attack by TBD 80 on the aldehyde functionality results in the formation of intermediate 83 (Figure 1.4.3.1.1), which is stabilised through hydrogen bonding interactions. Subsequent proton transfer could form the necessary enolate 84. Then, followed by regeneration of the aldehyde and expulsion of the guanidinium cation, ring closure can occur. The guanidinium species can also further activate the aldehyde through hydrogen bonding (Figure 1.4.3.1.1.85).
1.4.3.2. Morita-Baylis-Hillman reaction.

The ability of guanidines to catalyse Morita-Baylis-Hillman (MBH) reactions was discovered by Leadbeater *et al.* in their use of TMG to facilitate the reaction of methyl acrylate 81 and a variety of both aliphatic and aromatic aldehydes 82. Interestingly, the nucleophilicity of TMG dominated the reactivity of the reaction with no aldehyde aldol products being observed. Catalytic amounts of TMG gave rise to MBH products 83 in good yield with short reaction times (Scheme 1.4.3.2.1).

Scheme 1.4.3.2.1.

![Scheme 1.4.3.2.1.](image)
1.5. Synthetic methods for the construction of the guanidine functionality.

The synthesis of guanidines has come a long way from the landmark synthesis of tetrodotoxin 84 by Kishi in 1972\(^6\) in which the guanidine functionality was introduced by exposing amine 85 to dithiocarbonimidate 86 at elevated temperature and, then, exposing the intermediate product to AcNH\(_2\) to form the desired protected guanidine 87 in 18% yield over two steps (Scheme 1.5.0.1).

**Scheme 1.5.0.1.**

![Scheme 1.5.0.1](image)

1.5.1. Synthesis of acyclic guanidines.

Advances in the field have led to a myriad of methods for the installation of the guanidine functional group.\(^7\) In the past, the synthesis of guanidines involved the reaction of an amine 88 with an activated guanidine precursor followed by the deprotection of this moiety 89 to yield the corresponding free guanidine 90 (Scheme 1.5.1.1).

**Scheme 1.5.1.1.**

![Scheme 1.5.1.1](image)

The choice of guanidine precursor usually has depended on the reactivity of the amine involved; in the case of anilines, Lewis acid promoted reactions have been the most successful while for aliphatic amines, there is a much wider scope of guanidine precursor
available due to their greater nucleophilicity. Herein, we will discuss the classical methods for guanidine synthesis followed by more recent developments in the area.

### 1.5.1.1. Thiourea derivatives as guanidylating agents.

Classical methods for guanidine synthesis have tended to make use of either substituted thiourea or urea moieties being reacted with an amine and promoted by a variety of reagents. The earliest examples of thiourea being utilised as a guanidylating agent made use of the thiophilic Lewis acid HgCl₂ as a stoichiometric promoter.⁸⁸ Mercury(II) chloride is believed to act as a desulfurising agent forming an electrophilic carbodiimide, which in turn will be rapidly attacked when in the presence of a nucleophilic amine (Scheme 1.5.1.1.1).

Scheme 1.5.1.1.1.

This methodology is incredibly robust and synthetically useful, the reaction of a number of varying amines both aromatic and aliphatic with \( N,N\text{-bis-tert-butoxycarbonyl} \)thiourea in the presence of \( \text{NEt}_3 \) and HgCl₂ in CH₂Cl₂ afford the corresponding protected guanidines in good to excellent yields (Scheme 1.5.1.1.1. 78 – 92%). Acidic deprotection then yielded the corresponding guanidinium salts. The use of HgO as a replacement for HgCl₂ has been shown to be a viable alternative.⁸⁹

An interesting example of the synthetic utility of mercury-promoted guanidylation is the reaction between thiourea derivatives ⁹³ (Scheme 1.5.1.1.2) and \( N \)-iminopyridinium ylide, generated from compound ⁹⁴, to form unusual \( N \)-pyridinium benzoylguanidines products ⁹⁵. Bismuth salts were also shown to be effective in promoting this guanidylation reaction.
A useful method for the synthesis of \( N,N' \)-disubstituted aryl guanidines starts with Boc protection of thiourea 96 (Scheme 1.5.1.1.3) followed by exposure to trifluoroacetic anhydride (TFAA) which forms a highly reactive di-functionalised nitrogen atom.\(^9\) This substituent can in turn be displaced by addition of a nucleophile to form derivatised thiourea 97. Exposure of 97 to \( \text{HgCl}_2 \) promoted guanidylating conditions resulting in the formation of \( N,N' \)-disubstituted \emph{mono}-Boc protected guanidines 98 (Scheme 1.5.1.1.3).

However, the use of mercury is an obvious drawback in the above methodologies and other methods have been invented to combat this problem. Thus, in 2006 Cunha \emph{et al.} described the use of Bi(III) salts to promote the desulfurisation of protected thiourea 91 which is subsequently attacked by a nucleophilic amine species 88 constructing the appropriate protected guanidine 92 (Scheme 1.5.1.1.4) and expulsion of the Bi-S species.\(^9\)
The authors found that $\text{BiI}_3$ could be used in catalytic quantities (5 mol%) when $\text{NaBiO}_3$ was used as an oxidant. This method proved to be comparable with the $\text{HgCl}_2$ promoted guanidylation reaction when either aliphatic amines or activated anilines were used. However, the substrate scope did not include deactivated amines.

The use of $\text{Cu(II)}$ chloride salts has been reported to effect the conversion of protected thiourea $\text{91}$ into the corresponding guanidine $\text{92}$. Initial reports from Kim$^{88}$ et al. describe $\text{CuCl}_2$ being an ineffective promoter of guanidylation; however, more recent findings$^{93}$ suggest that $\text{CuCl}_2$ can be used as a Lewis acid with yields similar to those of the benchmark $\text{HgCl}_2$ reaction being obtained (Scheme 1.5.1.1.5). As expected non nucleophilic amines required heating and gave poor to moderate yields.

Copper(II) sulphate ($\text{CuSO}_4$) has also proven to be an active promoter in guanidylations reactions.$^{94}$ When used in conjunction with $\text{SiO}_2$ and $\text{NEt}_3$ in THF a number of aliphatic amines could be guanidylated with protected thiourea in adequate yields (Scheme 1.5.1.1.6). No aromatic amines were evaluated though indicating a lack of utility for the method with non-nucleophilic amines.
An attractive alternative to the utilisation of metal promoted guanidylolation is the use of Mukaiyama’s reagent 101 to assist in the desulfurisation of the thiourea. Mukaiyama’s reagent works best when nucleophilic amines are used (Scheme 1.5.1.1.7).\(^9\)

It has been shown that the choice of solvent can play a critical role in the reaction of the protected thiourea 91 with varying amines when using Mukaiyama’s reagent 101. The reaction of non-nucleophilic amines with thiourea 91 was shown to be much more effective in dichloromethane than dimethylformamide (as is the typical choice of solvent for this reaction), with yield increases of around 50% being achieved.

N-Iodosuccinimide (NIS) has also proven to be a viable choice in the guanidylation of an amine 88 with protected thiourea 91 (Scheme 1.5.1.1.8). In 2009 Smietana \textit{et al.} reasoned that thiophilic NIS, acting as a soft Lewis acid, should coordinate to the sulfur of the protected thiourea and in the presence of an amine and a base form the desired guanidine 92.\(^6\)
An array of amines was investigated with primary aliphatic amines giving excellent yields and hindered secondary amines giving moderate yields. When bis-Boc-S-methylisothiourea replaced bis-Boc-thiourea as the guanidylating agent higher yields were obtained for secondary amines.

An interesting metal free guanidylation procedure makes use of 2,4,6-trichloro-1,3,5-triazine (TCT or cyanuric chloride 102) as a promoter of desulfurisation of protected thiourea. Compound 102 when used in conjunction with N-methylmorpholine (NMM) and catalytic DMAP in THF activates bis-Boc-thiourea leading to efficient guanidine formation. TCT can be used in 0.33 equivalents due to the three available sites for activation (Scheme 1.5.1.1.9).
Upon exposure to sodium molybdate dihydrate (Na₂MoO₄·2H₂O) and hydrogen peroxide (H₂O₂, 30% in water), thioureas 91 are known to be converted into sulfonic acids 103 (Scheme 1.5.1.1.10).

Scheme 1.5.1.1.10.

\[
\text{NHR}^1 \quad \xrightarrow{\text{H}_2\text{O}_2, \text{Na}_2\text{MoO}_4\cdot2\text{(H}_2\text{O})} \quad \text{SO}_3\text{H} \quad \xrightarrow{\text{RNH}_2, \text{MeCN, rt}} \quad \text{NHR}^2
\]

Maryanoff et al. discovered that these sulfonic acid substrates 103 are then viable options as guanidylating agents. Upon exposure to nucleophilic amines the oxidised sulfur can be displaced to yield the desired guanidine 92 (Scheme 1.5.1.1.10). The reaction of several monosubstituted thioureas under these oxidising conditions was reported in good yields and these sulfonic acids 103 were shown to be thermally stable at room temperature. A range of amines were investigated for their efficacy in displacing the oxidised sulfur and good to excellent yields were reported. Elevated temperatures were required for either hindered or non-nucleophilic amines.

In the search for orthogonal protecting groups to those typically used in peptide synthesis and in particular peptides containing arginine residues two new functionalities have been discovered. 2,3,6-Trimethyl-4-methoxybenzenesulfonyl (104, Mtr) and 2,2,5,7,8-pentamethylchroman-6-sulfonyl (105, Pmc) groups have been designed to withstand cleavage conditions that would typically remove either Boc, Cbz or Fmoc protecting groups (Scheme 1.5.1.1.11).
Mtr or Pmc protected thiourea (for example 106) can be reacted with a range of amines under typical guanidylation conditions [Hg(ClO₄)₂ proved to be optimal] to form both Mtr or Pmc protected guanidines (for example 107) respectively (Scheme 1.5.1.1.11). These groups, as previously alluded to, are particularly useful in peptide synthesis incorporating guanidine containing arginine residues. Deprotection occurs under strong acidic conditions.

1.5.1.2. Coupling reagents.

In a number of cases the coupling reagent EDCI [1-ethyl-3-(3-dimethylaminopropyl) carbodiimide] has been shown to be able to promote guanidylation between thiourea derivatives and nucleophilic amines. In an example published in 2002, EDCI was used to effectively facilitate the desulfurization of thiourea 108 and subsequent guanidine 109 formation (Scheme 1.5.1.2.1). Compound 108 had been synthesised by reaction of benzylamine 110 and ethyl thiocyanatoformate 111 in CH₂Cl₂ affording the product in 2 h in a 98% yield.
Chapter 1

Introduction

Most of the amines employed were aliphatic in nature with only one example of a non-nucleophilic amine, aniline, being used. To remove the ethyl carbamate group typical methodologies failed.\textsuperscript{100} Interestingly, trimethylsilyl bromide under refluxing conditions in DMF turned out to be the conditions of choice in this deprotection. However, only a single yield of 95\% \textsuperscript{112} was reported for this deprotection step without a list of substrates being provided.

Another example found in the literature from 2007 also effectively uses EDCI to form substituted guanidines (Scheme 1.5.1.2.2).\textsuperscript{101}

Scheme 1.5.1.2.2.

In the example in Scheme 1.5.1.2.2., N-Pmc-isothiocyanate \textbf{113} is reacted with a variety of both primary and secondary amines to form substituted thioureas \textbf{114} in good to excellent yields. Subsequently, other amines were reacted with the substrate \textbf{114} separately in the
presence of the coupling reagent EDCI to form compounds 115. It is important to note the viability of forming derivatised guanidines in this manner. The relatively electrophilic isothiocyanate can react with a plethora of amines of varying nucleophilicites. However, the EDCI promoted step requires nucleophilic primary amines to obtain optimal results. By choosing the appropriate amines for each step the authors were able to synthesise a number of substituted guanidines which could then undergo deprotection of the Pmc group in acidic conditions to yield the guanidinium trifluoroacetate salts 116.

1.5.1.3. Metal-catalysed carbodiimide guanidylation.

The reaction between an amine and a carbodiimide is one of the most atom economical methods of synthesising guanidines and has been a fruitful area of research in recent years.112 Numerous examples of metal catalysed reactions between amines and carbodiimides have been published.102 In a 2012 publication it was reported that aniline 117 could be reacted with dicyclohexylcarbodiimide (DCC) and its derivatives 118 in the presence of a heterogeneous metal to form the corresponding guanidine 119. Initial investigations (Scheme 1.5.1.3.1) showed that nanocrystalline zinc oxide (nano ZnO) catalysed this reaction effectively and after a quick solvent screen it was found that non-polar, non-coordinating solvents such as toluene gave optimal results (yield 98%).

Scheme 1.5.1.3.1.

Interestingly, the use of commercial ZnO as opposed to nano ZnO gave drastically inferior yields (~ 5%). The nano ZnO could be recycled up to 6 times giving similar yields on each occasion without dropping activity. A wide variety of anilines and a number of carbodiimides could be reacted under similar conditions generating the required trisubstituted guanidines. The drawback of this chemistry, however, is that only a select few carbodiimides are both
stable and/or commercially available allowing only very particular substrates to be synthesised in this way. Hindered amines required higher temperatures for reactivity to occur. The ZnO is thought to activate the carbodiimide facilitating the nucleophilic attack from the amine.

In another report in 2012, Fe(OAc)$_2$ (2 mol%) was shown to catalyse this transformation between anilines 117 and carbodiimides 118 just as effectively as nano ZnO under similar conditions.$^{104}$ As in the previous report, both a wide range of aromatic amines and aliphatic amines were guanidylated in this manner. Similarly, the drawback is the lack of available carbodiimides to obtain a truly diverse library of guanidines.

### 1.5.1.4. Polymer supported guanidylation.

A number of methods for the solid phase syntheses of guanidines have been reported. The use of polymer supported reagents have a number of advantages namely allowing the removal of excess reagent, unreacted starting materials and unwanted by-products from the reaction mixture.$^{105}$

The utility of solid supported reagents in the preparation of guanidines has been demonstrated in the synthesis of $N,N',N''$-trisubstituted guanidines in a report by Drewry et al. in 1997 (Scheme 1.5.1.4.1).$^{106}$ The synthesis began with the preparation of solid phase supported reagent 120. This azide is then exposed to PPh$_3$ to form an iminophosporane which in the presence of PhNCS can undergo an aza-Wittig coupling forming the prerequisite carbodiimides 121 which are known to be stable in solid phase chemistry. Compound 121 can now be reacted with a variety of amines such as $N$-phenylpiperazine to form polymer bound guanidine 122. Under acidic conditions the desired guanidine can be cleaved from the resin to yield the final compounds 123 in good yield.
The synthesis of mono-substituted aryl guanidines can also be achieved using solid support chemistry (Scheme 1.5.1.4.2). The preparation of solid supported Boc protected thiourea can be thought of as a polymer bound guanidylating agent. In the presence of a promoting agent such as Mukaiyama’s reagent a range of amines could be reacted with the thiourea derivative to form polymer supported Boc protected guanidines. Upon exposure to TFA the guanidines could then be cleaved from the resin yielding the desired mono substituted guanidines as their trifluoroacetic acid salts.
1.5.1.5. S-Methylisothiourea as guanidylating agent.

The use of S-methyl-N,N'-bis-Boc-isothiourea 127 as a guanidylating agent has found success in a number of literature examples. Its ability to replace N,N'-bis-Boc-thiourea 128 has proven to be advantageous in a number of circumstances. In a discovery by Rozas and co-workers it was found that copper(II) salts could promote guanidylation of N,N'-bis-Boc-thiourea with a variety of amines but either gave either low or no yields for the analogous reaction with S-methyl-N,N'-bis-Boc-isothiourea.

However, in another publication by Terada et al. it was demonstrated that copper(I) salts could effectively promote guanidylation of both thiourea precursors (Scheme 1.5.1.5.1). In this work, a number of amines were exposed to both sets of conditions and in the two cases the protected guanidine products 129 were obtained in good to excellent yields (Scheme 1.5.1.5.1). This interestingly shows the specificity that promoters can sometimes have in guanidylation reactions and give an insight into why there is such a diverse literature for the synthesis of guanidines.

Scheme 1.5.1.5.1.

![Scheme 1.5.1.5.1.](image)

In an effort to efficiently synthesise a diverse variety of N,N',N''-trisubstituted guanidines 130, an effective phase transfer catalysed alkylation of protected guanidines 131 was unveiled (Scheme 1.5.1.5.2). A variety of amines 132 were reacted with S-methyl-N,N'-bis-Boc-isothiourea 127 in the presence of HgCl₂, as this is known in the literature to be very efficient in the preparation of protected guanidines.
Then, in a biphasic system of CH$_2$Cl$_2$ and H$_2$O the compounds were reacted with KOH, a phase transfer catalyst (Bu$_4$NI, 0.1 eq) and a number of alkylation agents 133 (Scheme 1.5.1.5.2). This process allowed the rapid formation of highly diversified guanidines 130 in good to excellent yields. This reactivity, however, was only reliable when both $R$ and $R'$ were not equal to H, as this led to non-specific alkylation at either nitrogen or, in some cases, to bis-alkylation.

In Ma’s synthesis of martinelllic acid 134, a novel method of guanidylation was devised. It was found that AgNO$_3$ is able to promote the guanidylation of S-methylisothiourea derivatives 135 with a variety of amines to form guanidine products 136 in excellent yield (Scheme 1.5.1.5.3).

The reaction was shown to work well with aliphatic amines, sterically hindered secondary amines and also with aniline. This new method was formulated due to the fact that hindered secondary amines are often difficult to guanidylate and initial experiments using typical...
guanidylation methodologies proved unfruitful. This method allowed the team to install the key guanidine functional groups with relative ease.

An interesting guanidylating agent designed by Du Bois and used in his synthesis of guanidine natural products is Tees (2,2,2-trichloroethoxysulfonyl) – protected imidochloride 137. This compound can be prepared as shown in Scheme 1.5.1.5.4.

Scheme 1.5.1.5.4.

1. CS$_2$, NaOH
2. Me$_2$SO$_4$

This reagent 137, although laborious to prepare, has shown to be an effective way of introducing guanidines (Scheme 1.5.1.5.5) which are to be used in C-H amination reactions. Romo has also made use of this reagent in his synthesis of the natural product phakellin.

Scheme 1.5.1.5.5.

1. NEt$_3$
2. HgCl$_2$, (Me$_3$Si)$_2$NH

1.5.1.6. $N,N',N''$-Trisubstituted guanidines as guanidylating agents.

Since 1998 it has been known that guanidines can be synthesised from guanidine precursors by coaxing one of the nitrogens into being an effective leaving group. This can be done effectively as discovered by Goodman and co-workers by using triflate derivatised guanidines (Scheme 1.5.1.6.1).
Firstly, either $N,N'$-bis-Boc-guanidine 140 or $N,N'$-bis-Cbz-guanidine 141 are synthesised. Subsequent exposure to triflic anhydride introduces a triflyl group to the remaining unsubstituted nitrogen atom of the guanidine moiety (Scheme 1.5.1.6.1, 142, 143).

The two carbamate protecting groups (either Boc or Cbz) pull electron density away from the central carbon atom of the guanidine. Nucleophilic attack can follow and the triflated amine can act as a leaving group (Scheme 1.5.1.6.2). The relative stability (due to the delocalisation of the ensuing negative charge) of this expelled group is what drives this reaction forward and allows these reagents to be effective as guanidylating agents. Sterically hindered aliphatic amines and primary amines work particularly well under these conditions; however, limited studies have been conducted on the efficacy of these reagents with electron deficient anilines. 115
The use of di(imidazol-1-yl)methanimine 147 as an effective guanidylating agent has also been shown to be synthetically useful in the preparation of derivatised guanidines.\(^\text{116}\) By exposing imidazole 148 (0.5 eq.) to cyanogen bromide (BrCN, 1.0 eq.), 147 can be synthesised in good yield (Scheme 1.5.1.6.3. \(\text{147} = 81\%\)).

**Scheme 1.5.1.6.3.**

![Scheme 1.5.1.6.3.](image)

The presence of two imidazole leaving groups facilitates initial displacement of a single imidazole by an amine nucleophile. These compounds 149 can then be isolated and exposed to a further equivalent of another amine generating structurally diverse guanidines 150 in acceptable yields (Scheme 1.5.1.6.3). The success of these reactions is dependent on the nucleophilicity of the attacking amines; electron deficient anilines did not react in this case (4-nitroaniline, 0% yield).\(^\text{116}\) Similar pyrazole derivatives have also been designed and shown to be effective as guanidylating agents.\(^\text{117}\) A further study showed the effects of electron withdrawing substituents on the pyrazole ring in forming guanidines.\(^\text{118}\)

Subsequent research in this area investigated the use of benzotriazoles 151a as a leaving group in guanidylation reactions.\(^\text{119}\) A comparative investigation was conducted on the influence of decreasing the electron density of the benzotriazole group using chloro 151b and nitro 151c groups (Scheme 1.5.1.6.4). Increasing the leaving group ability of the benzotriazoles by allowing them to facilitate the resulting negative charge which would arise from expulsion increased their reactivity towards amine nucleophiles.
1.5.1.7. Urea derivatives in guanidine formation.

As an oxygen analogue of guanidine, urea would seem like an obvious precursor in the synthesis of guanidines. However, urea has received much less attention in comparison to its sulfur analogue, thiourea, presumably due to its stable nature. The literature examples are typically either low yielding or have a low substrate scope. One such example is the synthesis of a library of quinoline guanidine derivatives 154 in the hope of discovering novel anti-inflammatory agents. Thiourea derivatised quinolines 155 were exposed to PPh3, CCl4 and NEt3 under reflux in CH2Cl2 using Appel type conditions to form crude carbodiimides 156 which, without purification, were exposed to a number of amines 157 in different solvent yielding $N,N',N''$-trisubstituted guanidines 154 in varying yields (Scheme 1.5.1.7.1). The inability to purify the intermediate carbodiimide is an obvious drawback. This reaction has hugely varying yields with some substrates giving yields of just 14%.

Scheme 1.5.1.7.1.

In an effort to synthesise 7-substituted pyrrolo[3,2-$d$]pyrimidines, 3-aminopyrrole derivative 158 was reacted with bis-protected pseudourea 159 in the presence of catalytic amounts of
AcOH in MeOH (Scheme 1.5.1.7.2). This led to guanidylated intermediate 160 which, upon exposure to NaOH, was deprotected and cyclised to form desired product 161.

Scheme 1.5.1.7.2.

Initial attempts to guanidylate amine 158 using a thiourea analogue of 159 also led to the desired product. However, as is typical with the reaction of aromatic amines and thiourea derivatives, HgCl$_2$ was required to promote the reaction. The authors decided that, as the compounds were to be used in biological testing the presence of ppm amounts of mercury was unacceptable and that the use of urea precursor 159 was a much safer alternative.

In an effort to synthesise cyanoguanidine derivatives 162 a novel method of guanidylation was discovered by Atwal and co-workers at BMS, Princeton. $N$-Cyano-$O$-phenylisourea 163 was found to react favourably with non-basic amines such as aniline 164 when AlMe$_3$ was used as a promoting agent (Scheme 1.5.1.7.3) to form derivatised ureas 165.
High yields were obtained when electron rich anilines 166 such as 4-methoxyaniline was used (90%), while electron deficient anilines such as 4-nitroaniline gave no reaction.

1.5.1.8. The Mitsunobu reaction to form guanidines.

The utility of hydroxyl groups as synthetic handles has been well established throughout chemical history. The ability to convert hydroxyl groups into varying substituents by means of the Mitsunobu reaction has proven to be ubiquitous in syntheses since its discovery in 1967\textsuperscript{125} as is discussed in the numerous reviews on the topic.\textsuperscript{126} As a means of guanidine introduction, the ability to replace primary hydroxy functionalities is particularly useful when it is advantageous to have hydroxy precursors as opposed to aliphatic amines.

Both thiourea guanidine precursors 167 and protected guanidines 168 can be reacted with primary alcohols 169 (Scheme 1.5.1.8.1) in the presence of triphenyl phosphine (PPh\textsubscript{3}) and diethylazodicarboxylate (DEAD) to form alkylated derivatives (Scheme 1.5.1.8.1. 170, 171).\textsuperscript{127}
Chapter 1

Introduction

Scheme 1.5.1.8.1.

This methodology has been used to synthesise protected arginine derivatives\(^{128}\) 172 (Scheme 1.5.1.8.2) and natural products\(^{129}\) in acceptable yields.

Scheme 1.5.1.8.2.

1.5.1.9. Cyanamides in guanidine synthesis.

A rather dated method for the synthesis of guanidines makes use of the formation of cyanamides and subsequent reaction with derivatised amines. Both functionalised anilines can be reacted with cyanamide to from aryl guanidines\(^{130}\) and, analogously, phenyl cyanamides can be synthesised and then further reacted with a variety of amines, also forming aryl guanidines.\(^{131}\)

The synthesis of \(^{11}\)C radiolabelled aryl guanidines 175 is of great importance as guanidines are involved in numerous biological activities and labelling them with short-lived positron emitters (\(^{11}\)C \(t_{1/2} = 20.3\) min) such as \(^{11}\)C would allow their use in both \textit{in vivo} positron emission tomography (PET) studies and \textit{in vitro} assays.\(^{130}\) Thus, the preparation of \(^{11}\)C labelled aryl guanidines was achieved using cyanamide chemistry (Scheme 1.5.1.9.1). Firstly, the appropriate aniline 176 was reacted with \(^{11}\)C labelled cyanogen bromide and, then, this
aryl cyanamide 177 was exposed to ammonia in different solvents to afford the desired products 175.\textsuperscript{130}

**Scheme 1.5.1.9.1.**

\[

\end{align*}
\]

In a report from Kim \textit{et al.}\textsuperscript{131} this reactivity was utilised in the synthesis of aryl guanidines which were required in their synthesis of inhibitors of the NF-κB transcription regulation related to TNF-α cytokine release. A number of anilines 178 were reacted with conc. nitric acid in ethanol at 90 °C to afford aryl guanidines 179 (Scheme 1.5.1.9.2).

**Scheme 1.5.1.9.2.**

178 & & 179 & 82\% \text{ (only yield reported)}
\end{align*}
\]

A more efficient method for the reaction of anilines and also aliphatic amines with cyanamides has recently been unveiled by Looper and co-workers at the University of Utah.\textsuperscript{132} Derivatised cyanamide 180 was first synthesised by reacting cyanamide with benzyl chloroformate 181 forming the Cbz protected cyanamide 182 (Scheme 1.5.1.9.3).

\end{align*}
\]
Chapter 1

Introduction

This was then converted into the potassium salt 180 by exposure to potassium methoxide in methanol. Compound 180 could then be activated in the presence of TMS-Cl and a base, forming a carbodiimide reactive intermediate 183 which can be nucleophilically attacked by a number of amines to form mono Cbz protected guanidines 184 (Scheme 1.5.1.9.4).

Scheme 1.5.1.9.4.

![Scheme 1.5.1.9.4](image)

Aliphatic nucleophilic amines gave the highest yields with short reaction times (15 min) while both hindered and non-nucleophilic substrates such as anilines required longer reaction times and gave lower yields. The Cbz group could then potentially be removed by Pd catalysed hydrogenation (Scheme 1.5.1.9.5); however, only 1 example of deprotection was reported.

Scheme 1.5.1.9.5.

![Scheme 1.5.1.9.5](image)

1.5.1.10. Copper catalysed cross coupling chemistry in guanidine synthesis.

Copper coupling chemistry has seen a renaissance in the past decade. The harsh conditions historically required for Ullmann reactions have been discarded and replaced by mild, copper catalysed reactivity. The ability to form C–N bonds in a facile manner is of clear importance in the synthesis of guanidines and copper coupling chemistry allows a type of umpolung reactivity in comparison to the typical methods of guanidine synthesis. As opposed to nucleophilic anilines reacting with a guanidine precursor, an aryl halide is exposed to a nucleophilic guanidine source. This reactivity allows for facile assembly of aryl guanidines.
As it is typical with copper coupling chemistry the exact mechanism of the catalytic cycle is still unclear. However, a possible catalytic cycle that would be in agreement with previous findings in copper chemistry has been suggested by Dawei Ma and co-workers at Shanghai Institute of Organic Chemistry (SIOC). It is known that α-amino acids and CuI can form chelate complexes such as 187 (Figure 1.5.1.10.1). The formation of the Cu(I)–amino acid species makes it more reactive towards oxidative addition and may also stabilize the oxidative addition intermediates thereby promoting the coupling reaction. Complex 187 may then coordinate to guanidine to give complex 188, whose oxidative addition to an aryl halide could afford Cu(III) complex 189. The presence of a base in the catalytic cycle could then result in the formation of 190 which upon reductive elimination could generated monoarylated guanidines and regenerate the Cu(I) species 187.

![Figure 1.5.1.10.1. Proposed catalytic cycle for copper catalysed guanidylation.](image)

Another plausible mechanism for copper catalysed coupling chemistry is depicted in Figure 1.5.1.3 and has been previously suggested. As occurs in the previous mechanism a Cu(I)
complex will be formed by coordination to the $\alpha$-amino acid ligand. Chelated Cu(I) may possibly coordinate to an aryl halide forming the $\pi$-complex 191 which would be electron deficient and more susceptible to amine nucleophilic attack giving 192 (Figure 1.5.1.10.2). Subsequent expulsion of the halide leaving group to form 193 and dissociation of the copper complex regenerate the active Cu(I) species and yields the desired product. Although it is not known exactly which is the actual mechanism both have been often used to explain results arising from copper coupling chemistry.

![Figure 1.5.1.10.2. Alternative catalytic cycle for copper catalysed guanidylation.](image)

In an investigation into the synthesis of benzimidazoles, the formation of aryl guanidines 194 by means of copper catalysed cross coupling chemistry was discovered (Scheme 1.5.1.10.1). 138 Aryl iodides 195 and guanidines 196 could be coupled together in the presence of Cul and ligand 197 to yield arylguanidines 194. This was the first report of its kind (with six examples) and was followed by investigations from other research groups developing further the result.
In 2010 a report from Antilla and co-workers at the University of South Florida described the formation of \(N,N'\)-disubstituted aryl guanidines 198.\(^{139}\) Guanidine nitrate 199 was chosen as the source of nucleophilic guanidine and a wide variety of aryl iodides 195 were selected as the coupling partners (scheme 1.5.1.10.2).

### Scheme 1.5.1.10.2

![Scheme 1.5.1.10.2](image)

Thus, in the presence of catalytic amounts of Cul (10 mol%), ligand 200 (\(N,N'\)-diethylsalicylamide, 20 mol%) and \(K_3PO_4\) in acetonitrile at 80 °C for 24 h, successful couplings between the two substrates were achieved with varying yields. However, mono arylated products could not be obtained with diarylation being observed in all cases (Scheme 1.5.1.10.2).

A report in 2011 also investigated the feasibility of forming C–N bonds through copper catalysis with the aim of preparing mono-arylated guanidines 201 (Scheme 1.5.1.10.3).\(^{140}\) A number of guanidine sources were investigated using both copper and palladium catalysts. Protected guanidines were chosen as the nucleophilic substrates due to their lower basicity and less reactive nature than guanidine itself. Palladium catalysis proved to be ineffective; however, initial experimentation with copper catalysts proved to be promising with a high
ratio of *mono*-arylated to diarylated products being observed. *p*-Methoxybenzyl (PMB) guanidine 202 was chosen as the most suitable form of protected guanidine. PMB protected guanidines were made from benzylamine and 2-methylthiopseudourea in 62–80% yields.

Scheme 1.5.1.10.3.

![Scheme 1.5.1.10.3.](image)

A range of α-aminoacid ligands were investigated for their efficacy in this cross coupling reaction as were varying copper sources, bases, solvent, temperature and time. Optimal results were observed when CuOAc (10 mol%), ligand 203 (20 mol%, proline) and K$_3$PO$_4$ in MeCN at 100 °C were employed for 3 hr. A wide variety of aryl halides 204 were coupled in good to excellent yields (Scheme 1.5.1.10.3). This is one of the few literature examples of C–N bond formation utilising copper coupling chemistry and an aryl triflate as a coupling partner.$^{141}$

Deprotection of PMB protected guanidines 201 was then accomplished by microwave irradiation in TFA at 100 °C (Scheme 1.5.1.10.4). This afforded the corresponding guanidines as trifluoroacetate salts 205 in excellent yields (Scheme 1.5.1.10.4. 89 – 95%). Due to the harsh nature of these deprotection conditions not a wide variety of functional group as substituents on the aryl ring were investigated.

Scheme 1.5.1.10.4.

![Scheme 1.5.1.10.4.](image)
In an attempt to form both symmetrical and unsymmetrical $N,N'$-diaryl guanidines (206 and 207 respectively) Ma et al. investigated the use of copper cross coupling chemistry. As with previous discoveries, initial investigations into the coupling of aryl halides with guanidines were concerned with optimising the reaction conditions to afford symmetrical $N,N'$-diaryl guanidines. Hence, aryl halides 208 and guanidine nitrate 199 were successfully coupled using a copper(I) source, an $\alpha$-amino acid ligand 209, base and solvent. The optimal reaction conditions are shown in Scheme 1.5.1.10.5.

**Scheme 1.5.1.10.5.**

As has been previously reported, the use of Cul (10 mol%) and $K_3PO_4$ in MeCN was optimal, with $N$-methylglycine (ligand 209, 20 mol%) being the ligand of choice. Under these conditions a number of aryl iodides could be diarylated in good yields and aryl bromides were also successfully coupled with guanidine nitrate in acceptable yields.

The poor ability of electron deficient aryl halides 210 to form diarylated products indicated the potential for forming unsymmetrical $N,N'$-diaryl guanidines in a sequential one pot process. Initial investigations coupled 4-nitroiodobenzene with guanidine nitrate 199 in conditions analogous to those reported for the previous diarylation. After 10 h, an electron rich aryl halide 211 (for example 4-methoxyiodobenzene) was added to the reaction mixture and allowed to react for a further 8 h (Scheme 1.5.1.10.6). As desired, the reaction resulted in the formation of unsymmetrical $N,N'$-diaryl guanidines 207 in reasonable yields.
In 2013 a three component copper catalysed coupling reaction between arylboronic acids 212, cyanamides 213 and amines 214 was reported. This reaction allows access to trisubstituted aryl guanidines 215 with a high potential for introducing diversity (Scheme 1.5.1.10.7).

This reaction is thought to proceed through transmetallation of copper(II) species generated from the oxidation of the Cu(I) salt in the presence of O₂. Coordination of the cyanamide and deprotonation, followed by tautomerisation, would ensue the generation of the highly electrophilic carbodiimide. This could then be attacked by the amine and subsequent oxidation of the Cu(II) species to Cu(III) could enable reductive elimination generating the guanidine product and regenerating the Cu(I) species. This possible catalytic cycle, as described by the authors is presented in Figure 1.5.1.10.3.
In an effort to synthesise derivatised guanidines, transition metal catalysed allylic substitution of N-Boc protected guanidines was investigated (Scheme 1.5.1.10.8). Miyabe and co-workers reported that both mono and double allylic substitution could occur. Guanidine bearing two electron withdrawing groups could act as a nucleophile in an allylation reaction to form the mono allylated product while tri-Boc-guanidine when exposed to similar conditions could afford the diallylated products.

Scheme 1.5.1.10.8.
The regiocontrol in the allylic substitution of unsymmetrical allylic substrates was investigated by using both Pd and Ir catalysis.

1.5.2. Synthesis of cyclic guanidines.

The ubiquitous nature of cyclic guanidine moieties throughout natural products\textsuperscript{12} and compounds of medicinal interest\textsuperscript{11} have ensured a wealth of methodologies designed for their facile synthesis. Herein we present some selected examples of literature methods for the formation of 5-, 6- and 7-membered rings incorporating the guanidine motif in their structure.

1.5.2.1. 5-Membered rings.

Among the most facile method for the synthesis of 5-membered rings containing guanidines is the use of $N,N'$-disubstituted-2-imidazolidinethione \textit{218} as a 5-membered analogous derivative of thiourea. In this way \textit{218} can be reacted with a variety of amines \textit{219} in the presence of a Lewis acid promoter such as HgCl$_2$ (Scheme 1.5.2.1.1) to form protected guanidines \textit{220}. Upon deprotection a wide variety of $N$-substituted-2-aminoimidazolines \textit{221} can be generated as has been shown by Rozas and co-workers in their development of $\alpha_2$-adrenoceptor ligands.\textsuperscript{145}

\textbf{Scheme 1.5.2.1.1.}

The oxygen analogue of \textit{218} has also shown to be of some synthetic utility in this type of reactions and no intermediates are isolated in this one pot procedure.\textsuperscript{146} Imidazolidin-2-one \textit{222} is exposed to dimethyl chlorophosphate \textit{223} forming intermediate \textit{224} \textit{in situ}, which in the presence of an amine will react to form the desired $N$-substituted imidazolines \textit{225}, displacing the halide leaving group (Scheme 1.5.2.1.2). An extensive study has not been
carried out on this type of reactivity with only few examples known. This methodology has also been applied to the synthesis of $N$-substituted-2-aminotetrahydropyrimidines.$^{146}$

**Scheme 1.5.2.1.2.**

$$\begin{align*}
\text{HN} & \quad \text{Cl} \\
\text{NH} & \quad \text{POMe}
\end{align*}$$

222 223  \xrightarrow{\text{CH}_2\text{Cl}_2, \text{reflux}} \left[ \text{Cl} \right] \quad \text{N} \quad \text{HN} \\
\text{CH}_2\text{Cl}_2 & \quad \text{RNH}_2 \\
\text{N} \quad \text{NH} & \quad \text{RNH}
\end{align*}$$

Perhaps the most atom economical method for the generation of 5-membered cyclic guanidines is the exposure of 1,2-diamines to cyanogen bromide. Initial reaction of an amine such as compound 226 with cyanogen bromide will form compound 227, in which the cyanamide functionality is now ideally located for a 5-exo-dig cyclisation to form the desired product 228 as demonstrated in the polymer supported chemistry shown in Scheme 1.5.2.1.3. Using this very simple chemistry a vast library of compounds could be synthesised ($R^1$ (26) x $R^2$ (26) x $R^3$ (26) x $R^4$ (42) = 738,192 total number of compounds).$^{147}$

**Scheme 1.5.2.1.3.**

$$\begin{align*}
\text{N} \quad \text{HN} & \quad \text{N} \\
\text{R}^1 & \quad \text{R}^2 \\
\text{N} & \quad \text{R}^3 \\
\text{N} & \quad \text{R}^4
\end{align*}$$

The synthesis of bicyclic guanidine containing compounds such as 2,3,5,6-tetrahydro-1$H$-imidazo[1,2-a]imidazole 229 has received considerable attention due to their unique
properties as superbases and application in organocatalysis as mentioned in Section 1.4.1. Initial investigations into their synthesis began with lengthy undesirable syntheses; however, in 1990 an efficient synthesis was derived from linear tri-amines $230$ being exposed to $\text{CS}_2$ in $p$-xylene (Scheme 1.5.2.1.4) to generate compound $231$ which then cyclises to afford thiourea $232$. $^{149}$

Scheme 1.5.2.1.4.

A more elegant synthesis for derivatised bicyclic guanidines results in chirally substituted products. $^{150}$ Initial amine tosylation of a 1,2-aminoalcohol $233$, followed by mesylation of the hydroxyl group generates aziridine $234$. Exposure to benzylamine (0.5 eq.) stereospecifically opens aziridine $234$ followed by opening of another equivalent of $234$ to generate triamine $235$. Treatment of $235$ with dimethyl trithiocarbonate, followed by methylation and heating, generates the desired bicyclic guanidines $236$ in five steps (Scheme 1.5.2.1.5).

Scheme 1.5.2.1.5.

Corey initially designed a synthesis of bicyclic guanidine compounds while investigating the enantioselective Strecker reactions catalysed by chiral bicyclic guanidines (see Section 1.4.1.1); however, his synthetic route involved nine steps. $^{55}$

$\alpha$-Chloroaldoxime-$O$-methanesulfonates, such as $237$, in the presence of nucleophilic amines are known to undergo Tiemann rearrangement $^{151}$ (the aza analogue of the Lossen
rearrangement\textsuperscript{152}). The resultant carbodiimide 238 is then available for nucleophilic attack by an external amine to generate both derivatised guanidines and imidazolines 239 (Scheme 1.5.2.1.6). This method was ingeniously used by Yamamoto et al. in their synthesis of a variety of guanidine containing compounds.\textsuperscript{151} A representative example is shown in Scheme 1.5.2.1.6.

Scheme 1.5.2.1.6.

As part of an ongoing programme into the synthesis of antibiotic mannopeptimycin \(\beta\), van Nieuwenhze and co-workers applied a Mitsunobu reaction to their synthesis of cyclic guanidine intermediate 240.\textsuperscript{129} Synthesis began with deprotection of protected amino alcohol 241 followed by guanidation using thiourea derivative 242 to afford compound 243. Consequent Mitsunobu reactivity closed the 5-membered ring in good yield forming the desired cyclic guanidine 244 (Scheme 1.5.2.1.7).
Interestingly, there was no aziridine side-product reported in the conversion of 243 into 244 even though the unprotected amine of the guanidine would presumably be more nucleophilic than the carbamate nitrogen. Presumably, the favourable formation of a 5-membered ring dominates the reactivity of this species.

In an interesting example of ring opening-ring closing reactions, a report in 2007 described the conversion of 2-aminopyrimidine derivatives 245 into cyclic guanidine moieties 246 as shown in Scheme 1.5.2.1.8.\(^\text{152}\)

Ensuring tosyl protection of the exocyclic amine of 2-aminopyrimidine facilitates alkylation of a ring nitrogen of the pyrimidine affording 245. Compounds of this sort are known to undergo ring opening and cleavage of the carbon framework connecting the two nitrogens of the pyrimidine.\(^\text{152,153}\) Exposure of 245 to MeNH\(_2\) and heating results in ring cleavage and then condensation of the guanidine functionality onto the amide resulting in an unusual route to cyclic guanidines 246.
Similar reactivity has been used effectively in Al-Mourabits synthesis of clathrodine 247 (Scheme 1.5.2.1.9). Initial investigations into the addition of a protected guanidine to an alkene 248 exposed to bromine did not result in guanidine addition to the olefin.

Scheme 1.5.2.1.9.

However, when the protected guanidine was replaced with 2-aminopyrimidine, initial displacement of a bromine atom and resulting ring closure to form 249 occurred. Treatment of 249 with NH$_2$OH.HCl in refluxing EtOH resulted in ring cleavage and cyclic guanidine 250 formation in good yield (Scheme 1.5.2.1.9).

In 2011 a novel one pot synthesis of cyclic guanidines was devised allowing for the formation of a diverse array of guanidine products 251. A variety of alkenes 252 were exposed to NBS, amines 253 and cyanamides resulting in the desired cyclic compounds (Scheme 1.5.2.1.10).

\]

One of the simplest approaches to the preparation of 5-membered guanidine containing molecules is a reaction pathway prevalent throughout nature, the biosynthesis of creatinine 255 (Figure 1.5.2.1.1).

Figure 1.5.2.1.1. Biosynthesis of creatinine

This biosynthesis process involves the condensation of the nucleophilic guanidine functionality of arginine 3 onto a carboxylate to form a five membered ring as is present in
creatinine,\textsuperscript{155} and this pathway can be easily replicated in the laboratory as displayed in Bazureau’s dispacamide A \textbf{256} synthesis (Scheme 1.5.2.1.11).\textsuperscript{156} Exposure of guanidine \textbf{257} to acidic conditions invoked ring closure to generate cyclic guanidine \textbf{258}.

In Danishefsky’s efforts towards the total synthesis of spiroleucettadine \textbf{259} a similar type of reactivity was employed.\textsuperscript{157} Initial guanidylation of \textbf{260} utilising compound \textbf{261} as a guanidylating agent, followed by ring opening of the lactone and then ring closing of the guanidine functionality resulted in a ring opened isomeric form \textbf{262} of the reported structure of \textbf{259} (Scheme 1.5.2.1.12).

1.5.2.2. Metal-catalysed ring closure.

In Du Bois' seminal work in stereospecific C-H insertion chemistry, a novel route for the synthesis of cyclic guanidines was designed.\textsuperscript{111} Oxidative C-H amination of \(N\)-Troc (Troc = 2,2,2-trichloroethoxycarbonyl) protected guanidines \(263\) to generate specifically 5-membered ring derivatives \(264\) over 6-membered rings was demonstrated (Scheme 1.5.2.2.1).\textsuperscript{158}

\textbf{Scheme 1.5.2.2.1.}

\begin{center}
\includegraphics[width=0.5\textwidth]{scheme1.5.2.2.1.png}
\end{center}

\textit{Troc} = 2,2,2-trichloroethoxycarbonyl.

This chemistry has a wide range of applications and has found use in both natural product synthesis\textsuperscript{159} and medicinal chemistry.\textsuperscript{44} The use of Tces as a protecting group along with Rh\(_2\)(esp)\(_2\) in catalytic quantities proved essential for reactivity. This strategy was effectively employed in the synthesis of the guanidine natural product gonyautoxin.\textsuperscript{160}

The use of diaziridinimines \(265\) as precursors for guanidines is a facile and atom economical route towards 5-membered cyclic guanidines \(266\) (Scheme 1.5.2.2.2).\textsuperscript{161} Reacting \(265\) with a variety of olefins \(267\) in the presence of CuCl in catalytic quantities can afford the desired guanidine products as described by Shi et al. Reactivity was shown to proceed regioselectively at terminal alkenes preferentially in the case of either dienes or trienes.

Chapter 1

Introduction

The reaction mechanism although still unknown is thought to proceed via homolytic cleavage of the N-N bond of 265 by CuCl, followed by addition of the nitrogen centred radical 268 to olefin 267 and subsequent C-N bond formation (269) and regeneration of catalyst CuCl (Figure 1.5.2.2.1).

![Proposed catalytic cycle of guanidylolation](image)

**Figure 1.5.2.2.1. Proposed catalytic cycle of guanidylolation.**

The exposure of vinyl aziridines 270 to catalytic amounts of Pd and PPh₃ in the presence of carbodiimides led to the generation of cycloaddition products 271 and 272 (Scheme 1.5.2.2.3). Initial Pd catalysed aziridine ring opening and subsequent π-allyl complex formation is presumably followed by guanidine formation and subsequent ring closure to yield the desired 5-membered rings. The mixture of stereoisomers obtained suggests that there is a η³-η¹-η³ interconversion of a π-allyl Pd complex. A recent report from the Stoltz laboratory presented a Lewis acid mediated variation of this reaction in which aziridines, with no vinyl appendages, are exposed to a variety of carbodiimides to produce iminoimidazolidines.
In 2008, Muniz et al. described the direct synthesis of bicyclic guanidines through unprecedented palladium(II) catalysed diamination with copper chloride as an oxidant. The synthesis of these bicycles occurs by means of a Pd catalysed intramolecular guanidine transfer to alkenes affording product (Scheme 1.5.2.2.4).

This method proves particularly effective in the formation of 5,5- and 5,6-bicyclic guanidines when guanidine is either Boc or Cbz protected.

In 2011, a report by Looper and co-workers exploited the reactivity of propargylguanidines in hydroamination reactions (Scheme 1.5.2.2.5). Two possible cyclisation pathways of propargylguanidine can be promoted leading to both 5- and 6-membered cyclic guanidines (276 and 277, respectively). The reactivity of these starting materials can be adapted into either product by choice of catalyst.
Metal catalysed cyclisations on alkynes typically favour 5-exo-dig pathways\textsuperscript{167} and therefore the ability to also form 6-endo-dig products is of particular interest. Looper \textit{et al.} have made use of this methodology in their synthesis of saxitoxin \textsuperscript{22}.\textsuperscript{168} During the preparation of the corresponding manuscript by Looper and co-workers, a similar type of reactivity was discovered by van der Eycken in an interesting set of reaction conditions to form cyclic guanidines.\textsuperscript{169} In this approach, propargylamines 278 were exposed to guanidylating conditions using AgNO\textsubscript{3} as the promoting agent (Scheme 1.5.2.2.6).

In the presence of silver (I) salts a 5-exo-dig was facilitated and, in one pot, the transformation of propargylamines 278 into cyclic guanidines 279 was effected. Sterically hindered propargylamines as well as \textit{N}-aryl propargylamines were also interestingly able to undergo this cyclisation pathway.
1.5.2.3. 6-Membered cyclic guanidines.

Although not as widely researched as the formation of 5-membered guanidine containing cyclic structures, the formation of 6-membered rings has received attention in the synthesis of numerous natural products and biologically active compounds.

The synthesis of \( N \)-substituted-2-amino-1,4,5,6-tetrahydropyrimidines (6-membered cyclic guanidines) has been reported by means of hydrogenation of the 2-aminopyrimidine precursor 280. In the search for integrin \( \alpha_\beta_3 \) antagonists Ajito et al. employed hydrogenation in acidic conditions catalysed by Pd/C generating cyclic guanidine 281 in an acceptable yield (Scheme 1.5.2.3.1).\(^{170}\)

![Scheme 1.5.2.3.1.](image)

Another similar reductive method for the synthesis of \( N \)-substituted-2-amino-1,4,5,6-tetrahydropyrimidines from 2-aminopyrimidines is utilised by Shen and co-workers in their use of triethylsilane and TFA.\(^{171}\) Initial discoveries gave both dihydro- and tetrahydropyrimidine products; however, upon optimisation, tetrahydropyrimidines were generated in poor to excellent yields (25 - 90% yield). A representative example is shown in scheme 1.5.2.3.2. converting amino pyrimidine 282 into guanidine 283.
In an effort to synthesise tricyclic guanidine 284 a reductive guanidylation method was formulised by Williams and co-workers.\textsuperscript{172} Initial guanidine precursor 285 was synthesised from urea 286 using Meerwein's salt (triethyloxonium tetrafluoroborate). The alkyl nitro functionality was then reduced using palladium catalysed hydrogenation to form the prerequisite primary amine which is now ideally located to displace ethoxide in an addition-elimination reaction (Scheme 1.5.2.3.3).

The facile synthesis of $N$-acyl cyanamides lends itself to an appealing method for the formation of tricyclic guanidines 287 by means of radical domino cycloaddition (Scheme 1.5.2.3.4).\textsuperscript{173} This method by Lacôte and co-workers is a sole literature example of the utilisation of radical chemistry to form cyclic guanidines.
Scheme 1.5.2.3.4.

Initial formation of a nitrogen centred radical 288 from the prerequisite azide 289 may react with the adjacent cyanamide forming a guanidine type radical 290 (Scheme 1.5.2.3.5). Subsequent interaction with the π-system forms the final six membered ring 291, while the presence of Bu₃SnH allows the re-aromatisation of the ring generating 292.

Scheme 1.5.2.3.5.

Overman and co-workers have effectively utilised the three component Biginelli reaction in their research towards the synthesis of 6-membered cyclic guanidines.¹⁷⁴ Utilising pyrazole guanidine 293, β-keto-ester 294 and derivatised aldehyde 295, in a three component Biginelli reaction, the desired cyclic guanidines 296 were formed in good yield (Scheme 1.5.2.3.6). These products, after further functionalisation, were converted into tricycle 297, the precursor for numerous guanidine natural products.
In an effort to synthesise similar tricyclic guanidine containing compounds, Nagasawa et al. designed a guanidine condensation type reaction leading to the generation of five rings in a single step.\(^1\) This impressive reaction was facilitated by an acid mediated deprotection of 298 and concomitant condensation of the guanidine and hydroxy functionalities onto the available ketone moieties (Scheme 1.5.2.3.7) to afford compound 299.

In Gin's exquisite synthesis of crambidine (300),\(^1\) the construction of the central cyclic guanidine was achieved by means of a [4+2] annulation between thioimidate 301 and vinyl carbodiimide 302 (Scheme 1.5.2.3.8). This route rapidly generated the core compound 303 which upon further functionalisation resulted in the completion of 300. Another key step was the hydroamination of an alkyne moiety (present in substrate 301) with derivatised 2-aminopyrimidine (present in substrate 303) as the nucleophile.
In 2002, Isobe et al. described their synthesis of 11-deoxytetrodotoxin 304 incorporating an interesting method of cyclic guanidine formation (Scheme 1.5.2.3.9). The acetate protected guanidine functionality present in precursor 305 had been installed using traditional methods.

Deprotection of the acetate groups (NH₄OH, MeOH, H₂O) followed by exposure to acidic conditions (TFA, H₂O) resulted in orthoester formation and guanidine cyclisation, displacing a methoxy group and forming a hemi-aminal. This is an impressive transformation due to the molecular complexity of both starting material and product.
It has been shown that bridged bicyclic allylic tertiary amines such as aza-norbornene 306 can add to an *in situ* generated carbodiimide (formed from thiourea derivative 307) to form a zwitterionic intermediate 308 (Scheme 1.5.2.3.10).^178

These strained systems are then ideally suited to undergo 1,3-diaza-Claisen rearrangement forming compound 309. The presence of an electron withdrawing substituent on the intermediate carbodiimide not only make the species more reactive to nucleophilic attack, but also stabilise the developing negative charge present in the zwitterionic species 308 (Scheme 1.5.2.3.10). A number of varying thioureas 307 were shown to be reactive towards carbodiimide formation when EDCI was used as a promoting agent.

In Harran’s study of the axinellamine natural products^179 a 6-membered thiourea analogue was used to introduce the guanidine functionality. Initially, compound 310 was reacted with carboxylic acid 311 to form intermediate 312 and, then, in the presence of oxalyl chloride cyclisation occurs to afford tricyclic compound 313 (Scheme 1.5.2.3.11). This presents an operationally simple and effective method for guanidine installation.
In the synthesis of the alkaloid alchorneine 314 a palladium mediated cyclisation of a prenyl functional group with cyclic guanidine 315 was developed (Scheme 1.5.2.3.12).\(^{180}\) Although two equivalents of palladium were required for the cyclisation to occur this represents an interesting method for the formation of functionalised pyrimidines.

Snider and co-workers incorporated a Michael addition followed by a condensation reaction to form the tricyclic natural product netamine E 316.\(^{181}\) This direct approach facilitated the synthesis of a number of natural products containing the same core. When Michael acceptor 317 in methanol under reflux was combined with guanidine, compound 316 was produced in 38\% yield (Scheme 1.5.2.3.13).
In an exceptionally elegant synthesis of saxitoxin 22 Looper et al. designed a highly elaborate cascade reaction to generate the key intermediate 318 starting from acyclic guanidine 319 (Scheme 1.5.2.3.14). The cascade begins with Ag(I) promoted ring closure of the benzyl protected guanidine onto the alkyne generating a 5-membered ring with an exocyclic olefin (Scheme 1.5.2.3.14., step 1). This olefin, under iodine activation (step 2), is then prone to nucleophilic attack by the acyclic guanidine functionality forming the 6-membered ring (step 3). Ensuing expulsion of the resulting secondary alkyl iodide, facilitated by the use of Ag(I) and acetic acid, would then generate highly functionalised intermediate 318.

Scheme 1.5.2.3.14.

In another approach towards saxitoxin 22 Nishikawa and co-workers have incorporated an ingenious cascade reaction in their synthetic route. This allows the rapid generation of complexity in their system. Exposure of alkyne 320 to pyridinium tribromide (PyHBr3) facilitates a bromocyclisation reaction which allows N-alkylation of the guanidine to occur (Scheme 1.5.2.3.15). This remarkable reaction generated a tricyclic core 321 in a highly stereospecific manner.

Scheme 1.5.2.3.15.
1.5.2.4. 7-membered rings.

In their synthesis of bicyclic guanidine alkaloid (+)-monanchorin 322 Sutherland et al. reported a late stage deprotection-cyclisation cascade to form the desired guanidine hemiaminal product 322.\(^{183}\) Acid mediated deprotection of the aldehyde, hydroxy and guanidine functionalities of 323 in one pot allowed for an efficient cyclisation reaction pathway, forming an unusual 7-membered guanidine containing ring (Scheme 1.5.2.4.1).

Scheme 1.5.2.4.1

In an analogous reaction to the ring opening–ring closing reaction of aziridines with carbodiimides to form five membered cyclic guanidines (see Section 1.5.2.2), 2-vinylpyrrolidines 324 can react with carbodiimides 325 to form 7-membered cyclic guanidines 326 (Scheme 1.5.2.4.2).\(^{184}\)
Scheme 1.5.2.4.2.

The reaction was shown to be optimal under slightly longer and harsher conditions (48 h, 5 psi N₂) than those required for the aziridine ring opening presumably due to the inherent relief of ring strain associated with aziridine ring opening. Formation of the π-allyl Pd complex 327 followed by guanidine induced ring closure and β-hydride elimination generate the desired vinyl guanidines 326.
2. Objectives

Rozas’ laboratory has been interested in the synthesis and biological evaluation of guanidine containing molecules for the past ten years. The application of guanidines as both minor groove binders (MGB) and $\alpha_2$-adrenoceptor ($\alpha_2$-AR) antagonists has been the focus of much of the research conducted. A number of promising results have been discovered in targeting the $\alpha_2$-AR, with a number of effective agonists and antagonists having been synthesised. $\alpha_2$-AR antagonists have proven to be a valid target for the alleviation of symptoms of Major Depressive Disorder (MDD, Section 3.1.2). For many years, these guanidines have been prepared by reacting the required anilines with $N,N$-bis-tert-butoxycarbonylthiourea in the presence of HgCl$_2$ to form the protected arylguanidines (Section 1.5.1.1.). The use of mercury in such reactions is an obvious drawback and it was decided that its use should be eliminated from the synthesis of biologically active guanidines in Rozas’ group.

2.1. Synthetic Chemistry.

i) An aim of this project is therefore to design and implement the synthesis of aryl guanidines without the use of HgCl$_2$. As described in the Introduction section there are a myriad of synthetic procedures available for such a synthetic endeavour. However, many of these procedures involve the use of toxic reagents, economically expensive precursors, require nucleophilic amines or have lengthy procedures. An aim of this project is therefore to design a synthesis for guanidine containing compounds that is:

1. Environmentally friendly.
2. Atom economical.
3. Cost Effective.
4. Scalable.
5. Simple to purify.

Once a suitable means of guanidylation is devised then it will be applied to the synthesis of biologically active guanidines such as $\alpha_2$-AR antagonists and MGBs. The synthesis of compounds which would be difficult to synthesise by mercury promoted guanidylation is also desirable. An ideal methodology is represented in Figure 2.1.1. An aryl halide $328$ would be
reacted with a guanidine surrogate to form 329 which could easily then be transformed into the desired guanidine containing moiety 330.

\[ \text{R} = \text{Low molecular weight, easily removable protecting group.} \]

**Figure 2.1.1. Desired guanidylation route.**

It has been postulated in Rozas’ group that 2-aminopyrimidine derivatives 331 may be suitable precursors for guanidine containing compounds 332 and it is hoped to discover a methodology which would enable this conversion (Figure 2.1.2.). Therefore, it is intended that 2-aminopyrimidine should be coupled with aryl halides and then a ring cleavage reaction is to be invented to afford the desired guanidine containing compounds X.

**Figure 2.1.2. 2-Aminopyrimidine derivatives as guanidine precursor.**

ii) Previously, the synthesis of 2-aminoimidazoline derivatives 333 has been investigated as cyclic guanidine derivatives by Rozas and co-workers with significant success. The ethylene linker between the two guanidine nitrogen atoms adds a hydrophobic element to the guanidine functionality and also disrupts the typical hydrogen bonding interactions associated with guanidines. With our plans to investigate the cleavage of the 2-aminopyrimidine ring system 331 to yield guanidine a subsequent aim of this project is to investigate the synthesis of 2-aminotetrahydro-1,4,5,6-pyrimidines 334. This would increase the hydrophobic interaction by increasing the size of the alkyl linker bridging the two nitrogen atoms (Figure 2.1.3.).
Figure 2.1.3. Increasing hydrophobic interactions by accessing 2-aminotetrahydro-1,4,5,6-pyrimidine derivatives 334.

Importantly, the synthesis of 2-aminotetrahydro-1,4,5,6-pyrimidines 334 is to follow the same criteria as outlined for an ideal guanidine synthesis.

2.2. Guanidine Natural Product derivatives as biological targets.

A wide variety of guanidine natural products such as palau’amine 21, saxitoxin 22 and dibromophakellin 23 contain the spirocyclic guanidine aminal backbone 19 (Figure 2.2.1). Another aim of this project is to design and implement a scalable, efficient and easily functionalised route to this core, centred on a cascade reaction designed in Rozas’ group. In particular, dibromophakellin 23 is known to be an $\alpha_2$-AR agonist and it would be of considerable interest to design a synthesis of aminal 19 which could be easily derivatised to enable analogues of 23 to be synthesised.

Figure 2.2.1. Cascade reaction to access spirocyclic guanidine aminal moiety
2.3. Pharmacology.

Novel guanidine containing compounds designed by new methodologies are then to be tested for biological activity as $\alpha_2$-AR antagonists. The $\alpha_2$-AR binding affinity (expressed as $pK_i$) for the synthesised compounds is to be determined firstly in human brain tissue. Next, those compounds with strong enough binding to the receptor ($pK_i > 6$) will undergo $[^{35}\text{S}]\text{GTP}\gamma\text{S}$ assays (as discussed in Section 4.9), also in human brain tissue, to investigate the activity of the compounds as agonists, antagonists or inverse agonists. This work is to be conducted in collaboration with Dr. Luis F. Callado at the Department of Pharmacology of the School of Medicine of the Basque Country University (EHT, Leioa, Spain).

2.4. Araiosamine Natural Products.

As part of a Fulbright scholarship obtained, research into the synthesis of the araiosamine family of guanidine – indole natural products will be conducted in the Baran laboratories at The Scripps Research Institute, USA.

3. 2-(Arylamino)-tetrahydro-1,4,5,6-pyrimidines.

3.1. Introduction.

The search for biologically active guanidine containing molecules has been the foundation of research in Rozas’ group for the past ten years. The vast possible interactions of guanidine in the mammalian body make it an exciting functional group to utilise. Two research areas in particular where promising results have been made are the utilisation of guanidine containing molecules as DNA minor groove binders and $\alpha_2$-adrenoceptor ligands. In the following section a brief introduction to both therapeutically relevant fields will be discussed and how this research project aims to synthesise new guanidine containing molecules to probe unexplored biological areas.

3.1.1. DNA minor groove binders.

DNA minor groove binders (MGBs) are compounds which can interact favourably with the minor groove of DNA (Figure 3.1.1.1).

Figure 3.1.1.1. The helical structure of DNA (a), the negatively charged phosphate backbone (b) and selected examples of minor groove binders 337 and 338 developed in Rozas’ laboratory (c).
The helical structure of DNA contains two grooves both the major and the minor forms, and the walls of these grooves are lined up by a negatively charged phosphate backbone (Figure 3.1.1).186

The minor groove is the target for many transcription factors and it has been shown to exhibit a negative potential; hence, this is an appealing target for compounds aiming to interfere with the replication of cells such as anticancer or antiprotozoal agents.188,189 At physiological pH guanidine derivatives (pKₐ values around 8 to 10) will be protonated with their positive charge being delocalised over the entire functionality. Previous research in Rozas' group has shown the efficacy of both di-aryl bis-guanidine and bis-2-aminoimidazolidine type of ligands as effective MGBs.190

3.1.2. α₂-Adrenoceptor ligands.

The α₂-adrenoceptors (α₂-ARs) are G-Protein Coupled Receptors (GPCR) associated with the heterotrimeric Gₛ protein. As is typical for a GPCR, α₂-ARs are comprised of seven transmembrane α-helices, an intracellular domain and a ligand binding domain. There are three highly homologous subtypes comprising of the α₂A, α₂B and α₂C receptors. α₂-ARs can be found both pre- and postsynaptically in the brain and, in particular, the prefrontal cortex has a high population of presynaptic α₂-ARs. Activation of presynaptic α₂-AR by its natural agonist noradrenaline (NA) leads to inhibition of NA release from the presynaptic neuron; hence, these receptors are modulators of the levels of NA in the synaptic cleft (Figure 3.1.2.1).191

![Figure 3.1.2.1](image.png)

Figure 3.1.2.1. Schematic representation of the α₂-AR and the effect of its activation by NA (represented by red circles).191,192
Antagonism of the $\alpha_2$-ARs has been linked with treatment of a variety of medical conditions such as schizophrenia, bi-polar disorder and major depressive disorder. The most basic description of depression states that reduced levels of monoamine in particular areas of the brain leads to symptoms of depression. This is known as the Monoamine Theory and has been in existence since the 1960s. This analysis although hugely oversimplified has been the target of most of the therapeutics aiming to combat depression. The majority of the commercially available antidepressants are selective serotonin reuptake inhibitors (SSRIs) which also act by elevating levels of monoamines in the brain. Examples include fluoxetine (Prozac ©) a blockbuster drug.

As $\alpha_2$-ARs are modulators of levels of NA in the synaptic cleft antagonism of this receptor can influence such levels, therefore potentially making it a viable target for antidepressants. In Rozas’ group a number of both guanidine and 2-aminoimidazolidine containing compounds have shown to be effective antagonists of $\alpha_2$-ARs and these have potential as antidepressants. Examples of $\alpha_2$-AR antagonists with good $pK_i$ values (a measure of the level of inhibition of the ligand for the GPCR receptor) are displayed in Figure 3.1.2.2. (compounds 339, 340 and 341). The larger the $pK_i$ value, the greater the molecule’s affinity for the receptor.

\[ \text{Figure 3.1.2.2. Selected examples of } \alpha_2-\text{AR antagonists.} \]

This very brief description of the role that guanidine derivatives can play in medicinal chemistry tries to highlight the relevance of designing and achieving new synthetic routes for the efficient, environmentally friendly and cost effective synthesis of aryl guanidines which may be used as MGBs or $\alpha_2$-AR antagonists; and this is the fundamental aim of this project.
3.2. Extending the chain: the synthesis of derivatised 2-(arylamino)-tetrahydro-1,4,5,6-pyrimidines.

From the brief introduction above we have described how both guanidines and 2-aminoimidazolines have proven to be useful functionalities in the context of medicinal chemistry research in Rozas’ group. The idea to extend the alkyl chain linking the two nitrogen atoms of the imidazolidine heterocycles was an appealing one. The extra steric bulk and lipophilicity inferred by an extra methylene functionality could potentially alter the binding interactions in a favourable manner leading to more effective biologically active agents (Figure 3.2.1.1). This chemical space has previously never been explored for either MGBs or α2-AR antagonists.

3.2.1. Preparation of N-aryl-2-aminopyrimidines

Synthetically, 2-(arylamino)-tetrahydro-1,4,5,6-pyrimidines 342 could be accessed from their pyrimidine analogues 343 by a reductive procedure (Figure 3.2.1.1).

![Figure 3.2.1.1. Design of tetrahydro-1,4,5,6-pyrimidine containing molecules.](image)

From a retrosynthetic standpoint there are two possible disconnections to form these molecules; the combination of anilines 344 with 2-chloropyrimidine 345 (Figure 3.2.1.2, route a) or the palladium catalysed addition of 2-aminopyrimidine 346 to aryl halides 347 (Figure 3.2.1.2, route b). In order to achieve the most efficient method it was decided to undertake a comparative study between the two coupling approaches.
Very few literature examples exist for the efficient uncatalysed addition of anilines to 2-chloropyrimidine and these examples suffer from poor yields typically obtaining the desired product in below 50% yield. Therefore, the need for the use of Buchwald-Hartwig palladium catalysed amination chemistry seemed evident.

In 1995 both Buchwald\(^{199}\) (MIT) and Hartwig\(^{200}\) (then Yale, now UC Berkley) published methods for the Pd catalysed coupling of aryl halides with amines to form aniline containing compounds. This was a major breakthrough in the field of organic chemistry, allowing rapid formation of potentially one of the most important bonds in the pharmaceutical industry: the C–N bond.

The Pd catalysed coupling between an aryl halide and an amine begins with the formation of a Pd(0) species typically from a commercially available Pd precatalyst such as Pd\(_2\)(dba)\(_3\). Dissociation of initial ligands to supply vacant coordination sites occurs followed by binding of phosphine ligands to the Pd centre.\(^{201}\) The binding of these ligands increases the electron density of the metal which accelerates the oxidative addition step. This step involves the insertion of Pd into the C–halogen bond to form two new bonds. The coordination number of Pd is 4 and hence to form a stable 18 e\(^-\) complex it requires four ligands donating 2 e\(^-\) each and the use of the d\(^{10}\) (4d\(^8\) and 5s\(^2\)) electrons of Pd.\(^{201}\)
Once this relatively stable complex has formed, coordination of the nucleophilic amine to the metal centre can occur, increasing the acidity of the amino protons, followed by deprotonation by a base (Figure 3.2.1.3, blue cycle). This is the most widely accepted interpretation of the catalytic cycle, but other suggestions propose initial binding of a nucleophilic base to the Pd centre before coordination of the amine, as is seen in other catalytic cycles (Figure 3.2.1.3, green cycle). These two interpretations still exist for the mechanism of this aspect of the catalytic cycle and there is experimental evidence for both routes.\textsuperscript{202,203} Small changes in reaction conditions have been proposed to have differing effects on this step. For example, when non nucleophilic bases such as Cs\textsubscript{2}CO\textsubscript{3} or K\textsubscript{3}PO\textsubscript{4} are utilised, the catalytic cycle is believed to follow the blue cycle in Figure 3.2.1.3.

Deprotonation of the amine and subsequent expulsion of the halogen leave a Pd(II) species bound to the incoming amine and the aryl functionality. Then, reduced electron density of the metal centre and the bulkiness of the ligand, facilitate reductive elimination to ensure regeneration of the L\textsubscript{n}Pd complex and expulsion of the new C–N bond containing compound. There are a number of factors affecting the efficacy of this highly effective synthetic transformation. The choice of ligand, base and solvent are all critical to the success of the reaction but each condition in turn also depend on the choice of substrates to be coupled.\textsuperscript{204}
Our experimentation began with the coupling of aniline 164 with 2-chloropyrimidine 345. Initially, the coupling of the two substrates was attempted without the use of Pd catalysis. As had been expected this generated the desired product 353 in poor yield (Table 3.2.1.1, entry 1). Systematically, each of the variables were changed and analysed including ligand choice (Table 3.2.1.1, entries 2 - 7), base (Table 3.2.1.1, entries 8 - 10), solvent (Table 3.2.1.1, entries 11 - 13) temperature (Table 3.2.1.1, entries 14 and 15). Catalyst and ligand loadings were also investigated (Table 3.2.1.1, entries 16 and 17). The reaction was also allowed run for an extended time period with little improvement in isolated yield being noted (Table 3.2.1.1, entries 18 and 19). The initial problem with reactivity was the poor level of conversion of starting material into product. After extensive optimisation for this reaction, as presented in Table 3.2.1.1, it was found that the ideal conditions for the coupling of our particular systems were: Pd$_2$(dba)$_3$ (2 mol%), Xantphos 352 (3 mol%), NaO-t-Bu in toluene at 95 °C for 12 h (Table 3.2.1.1, entry 16). A discussion on the role of each of the variables will be presented in a comparative manner at the end of this section.
With our optimised conditions in hand, we decided to test the substrate scope of this reaction by choosing a variety of electronically differing (Table 3.1.1.2, entries 2-8) and sterically differing...
anilines (Table 3.1.1.2, entries 1 and 8). The yields obtained were typically poor to good with electron deficient anilines noticeably underperforming as coupling partners (Table 3.1.1.2, entries 7 and 8). It was noted that in the case of electron deficient anilines, the use of K$_3$PO$_4$ as base was highly beneficial. An extensive screening of substrates was not undertaken in this step due to the initially poor results obtained and, hence, it was thought to be advantageous to turn our attention to the analogous couplings of 2-aminopyrimidine with aryl bromides (route b in Figure 3.2.3). This ‘inverse’ reactivity was hoped may lead to more satisfactory results.

The Pd-catalysed reaction between bromobenzene 356 and 2-aminopyrimidine 346 was optimised using the same optimisation process that we had employed in our first example by systematically changing all possible conditions including ligand (Table 3.2.1.3 entries 2 - 7), base (Table 3.2.1.3 entries 8 - 10), solvent (Table 3.2.1.3 entries 11 - 12), temperature (Table 3.2.1.3 entries 13 and 14), catalyst loadings (Table 3.2.1.3 entries 15 - 18) and time (Table 3.2.1.3 entries 19 and 20). Gratifyingly, it was immediately noticed that the yields were higher for this system than for our initial coupling reactions between aniline and 2-chloropyrimidine.

2-(Arylamino)-tetrahydro-1,4,5,6-pyrimidines.

The optimised conditions for the coupling of anilines with 2-chloropyrimidines also proved to be the preferred method to couple bromobenzene 356 with 2-aminopyrimidine 346 producing the desired N-phenyl-2-aminopyrimidine 353 in a highly satisfactory 98% yield (Table 3.2.1.3, entry 18).

Encouraged by this promising result a more extensive substrate scope was investigated for this coupling reaction. Electronically and sterically differing aryl bromides were exposed to these coupling conditions to afford a diverse library of N-aryl-2-aminopyrimidines (Table 3.2.1.4.).

ª 2-Aminopyrimidine (2 mmol), NaOt-Bu (2 mmol), aryl halide (1 mmol), Pd₂(dba)₃ (2 mol%), Xantphos (3 mol%), toluene (1 mL mmol⁻¹ aryl halide). b K₃PO₄ used as base. c 2 g scale.

The substrate scope displayed in Table 3.2.1.4 portrays the utility of the coupling of aryl bromides 357 with 2-aminopyrimidine 346 under the optimised conditions. Electron
withdrawing (Table 3.2.1.4, entries 8-10), electron donating (Table 3.2.1.4, entries 2-4) and sterically differing (Table 3.2.1.4, entries 1 and 11) substituents on the aryl bromide were all well tolerated under these conditions. The reaction between bromobenzene 356 and 2-aminopyrimidine 346 was also replicable on a multi-gram scale (Table 3.2.1.4, entry 12) and afforded a single highly crystalline solid after simple recrystallisation techniques (Figure 3.2.1.5).

![Figure 3.2.1.5. Highly crystalline N-phenyl-2-aminopyrimidine 357.](image)

The significant differences in the results obtained with these two coupling approaches can be explained by an analysis of the reaction mechanism in each case. Oxidative addition into a C–Cl bond of a heterocycle is known to be a slower process than that of their phenyl carbon bromine analogues (Scheme 3.2.1.1). There are a number of reasons for this such as the rate of insertion into C–halogen bonds is known to be faster for C-Br over C-Cl. Moreover, the presence of a ring nitrogen on the pyrimidine scaffold have a deleterious effect on the oxidative addition step due to their ability to interact with the metal centre. The ability for pyrimidine systems to be used as ligands in Pd cross coupling reactions is testament to this fact. It was decided not to examine the use of 2-bromopyrimidine as a coupling partner with anilines because although it may be a better coupling partner than 2-chloropyrimidine 345 with anilines, it would most likely be of less synthetic utility than the coupling of aryl bromides with 2-aminopyrimidine 346.
A number of factors proved essential for the reactivity of both systems. Interestingly, the use of Xantphos 352 was critical for the success of this reaction as has previously been demonstrated for the coupling chemistry of π-deficient heterocycles. The use of bidentate ligands such as Xantphos 352 have been widely studied for a variety of Pd catalysed transformations. Ligated Pd(0) species 361 has increased electron density on the metal centre due to the electron rich bidentate phosphine ligand. Xantphos' wide bite angle (the chelation angle between the ligand and the metal centre, see Figure 3.2.1.6) also aligns the appropriate molecular orbitals of Pd for facile oxidative insertion into an aryl halide bond (Figure 3.2.1.6, 362). This oxidative addition induces an increase in oxidation number for Pd from Pd(0) to Pd(II). In our case, utilisation of a bulky bidentate ligand such as Xantphos 352 also could prevent interactions between the nitrogenous backbone of pyrimidine and the metal centre.

Additionally, the use of Xantphos 352 plays a critical role in reductive elimination. The oxidation number of the metal decreases by two, there is an increase in the d-electron count by two and a decrease in the overall number of valence electrons by two (Figure 3.2.1.7).
Bidentate Pd(II) Xantphos complexes are more unstable than their bi-coordinated Pd(0) counterparts due to the large bite angle which makes it a very strained, crowded tetra-coordinated system. This wide bite angle therefore facilitates reductive elimination of the aryl and amino groups cis one to each other as it pushes them together to regain its more stable Pd(0) form. There is a vast precedence in the chemical literature for the enhancement of the rate of reductive elimination by the utilisation of ligands with wide bite angles.

In both Table 3.2.1.1 and Table 3.2.1.3, it was noted that NaOt-Bu (pKa_H = 17) was the optimal base to use. When electron withdrawing functionalities were present in the reaction mixture it was noted that K_3 PO_4 (pKa_H = 12) gave better results than NaOt-Bu. It has been noted that the rate of Pd catalysed amination reactions is often dependent on both the concentration and the nature of bases utilised for electronically differing aryl halides. It would appear that subtle differences in the choice of base can play an important role in these reactions and that these small differences have not been fully explained to date.

As it has been previously reported in the literature we have observed that the use of an extra equivalent of ligand, relative to those of Pd, was beneficial (Table 3.2.1.3, entry 16) giving an increase in the isolated yield of product. It has been hypothesised that an extra equivalent of ligand is often necessary in order to stabilise the Pd catalyst in difficult cases in which long reaction times are required or when a high turnover number (TON) at the metal centre is desired.

In conclusion, the optimised Pd catalysed coupling of aryl bromides and 2-aminopyrimidine and the ‘inverse’ of this reaction, the coupling of anilines with 2-chloropyrimidine, has now been documented. The outcomes indicate that the first of these two reactions gives more favourable results affording higher overall isolatable yields of products. With this information in hand we then set our objectives on the development of a reductive methodology to
transform our \( N \)-aryl-2-aminopyrimidine library into their corresponding 2-(arylamino-tetrahydro-1,4,5,6-pyrimidine analogues.

### 3.2.2 Reduction of the pyrimidine moiety to form 2-(arylamino)-tetrahydro-1,4,5,6-pyrimidines.

The transformation of \( N \)-alkyl-2-aminopyrimidine derivatives into their reduced guanidine counterparts is well catalogued.\textsuperscript{217} To date no previous research for the transformation of \( N \)-aryl-2-aminopyrimidine exists in the chemical literature (Figure 3.2.2.1).

![Diagram](image)

**Figure 3.2.2.1.** Retrosynthesis of \( N \)-aryl-2-amino-1,4,5,6-tetrahydropyrimidines.

The use of Pd catalysed hydrogenation to reduce the pyrimidine ring was an appealing idea and adhered to our plans for an atom economical, environmentally friendly and cost effective synthetic method.

The reductive hydrogenation of \( N \)-alkyl-2-aminopyrimidine derivatives was described by Ajito *et al.* when synthesising antagonists of Integrins \( \alpha_\text{v}\beta_3 \) and \( \alpha_{\text{IIb}}\beta_3 \) for the treatment of coronary thrombosis (Scheme 3.2.2.1).\textsuperscript{170}
This reaction was performed under one atmosphere of hydrogen in what would appear to be non-forcing conditions. The desire to emulate such results in our system led us to begin our synthetic explorations with the exposure of N-phenyl-2-aminopyrimidine to Ajito’s conditions.

Utilisation of Ajito’s conditions for our system gave initially promising results generating the desired product in 63% yield (Table 3.2.2.1. entry 1). Optimisation of these conditions indicated that the use of MeOH as a solvent proved highly beneficial most lightly due to the lack of solubility of protonated N-phenyl-2-aminopyrimidine in H$_2$O (Table 3.2.2.1. entries 1 – 5). Additionally, the pK$_{a1}$ of N-phenyl-2-aminopyrimidine is approximately 3$^{218}$ and therefore this compound should be protonated when exposed to 1M HCl. This is obviously an
important driving force for this transformation since a control reaction displayed no reactivity when HCl was omitted from the reaction vessel (Table 3.2.2.1, entry 7). A slight increase in the molarity of HCl used and the Pd/C loading also proved advantageous leading to the optimal conditions (Table 3.2.2.1, entry 6).

These conditions were then applied to our library of N-aryl-2-aminopyrimidines. In each case the pyrimidine ring was reduced to its alkyl analogue (Table 3.2.2.2, entries 1 - 6, 11); however, a number of side reactions occurred under these hydrogenative conditions. When 2-(3-bromophenyl)aminopyrimidine 358f was exposed to these reductive settings, unsurprisingly, the bromine atom was replaced with a hydrogen atom (Table 3.2.2.2, entry 7). This is expected as halides are known to be unstable in Pd catalysed hydrogenation due to the ability of Pd to insert into a C–halogen bond.201

Other results of interest were the reduction of both the meta and para nitrile substituents on the phenyl ring of compounds 358h and 358i respectively (Table 3.2.2.2, entries 9 and 10). This type of reduction of nitriles is known;219 however, the result obtained from the reduction of the ortho nitrile substituted compound 358g was interesting. Although the meta and para nitrile substituents were easily reduced, the ortho nitrile functionality was attacked by the formed guanidine functionality to form the tricyclic compound 367g (Table 3.2.2.2, entry 8).

\(^a\) N-phenyl-2-aminopyrimidine (1 mmol), Pd/C 10% (50 mg) MeOH (4 mL), aq. HCl (1M, 1 mL). \(^b\) Concomitant reduction of the nitrile moiety.

In conclusion, a highly atom economical and efficient method for the synthesis of 2-(arylamino)-tetrahydro-1,4,5,6-pyrimidines has been developed.
4.2-Aminopyrimidines as a guanidine precursor.

4.1. Introduction.

From the introduction of this thesis (Chapter 1) it is evident the multitude of synthetic procedures available to introduce the guanidine functional group. All of these methods have merit in different circumstances. For instance, if one requires the synthesis of $N,N',N''$-trisubstituted guanidines the use of Neuville's method (Scheme 1.5.1.10.7) would be advisable or if one would require the synthesis of $N$-alkylated guanidines it would be advantageous to use Mukaiyama's reagent 101 (Scheme 1.5.1.1.7).

However, in the context of synthesising aryl guanidines (Figure 4.1.1) for use as $\alpha_2$-AR antagonists or as MGBs then there is no particularly effective or atom economical method for their production.

![Figure 4.1.1. Retrosynthesis of aryl guanidines.](image)

Figure 4.1.1. Retrosynthesis of aryl guanidines.

It was therefore intended to design and implement a synthetic procedure that would introduce such guanidine functionality in an expedient and robust manner.

4.2. Initial investigations into coupling chemistry.

The ability for an aryl halide to be directly transformed into the corresponding aryl guanidine is unknown in the chemical literature. Previous attempts to coax this reactivity utilising copper chemistry have resulted in diarylation of guanidine (Section 1.5.1.10). However, this reaction could potentially work if a Pd catalysed system is utilised considering that a more rigid metal ligand interaction may prevent the guanidine binding to the metal centre, as is known to occur, For instance, in certain metal catalysed coupling reactions guanidine derivatives are utilised as ligands.
Preliminary attempts to couple bromobenzene 356 with guanidine hydrochloride 373 were unsuccessful with no observable product being formed (Table 4.2.1, entries 1 - 4). It was hoped that the use of bidentate Xantphos 352 might prove useful in preventing the binding of guanidine to the palladium metal allowing the desired reactivity to occur; however, no such result was obtained (Table 4.2.1, entries 5 - 8). It was therefore deemed logical to focus our attention on finding a guanidine surrogate which could be easily coupled with aryl halides and then deprotected as appropriate to yield the guanidine functionality.

### 4.3. The 2-aminopyrimidine scaffold as a guanidine surrogate.

As detailed in Section 1.5.2, Al-Mourabit has shown the potential for 2-aminopyrimidine derivatives to act as guanidine surrogates.\(^{153b}\) With our recently prepared library of \(N\)-aryl-2-
aminopyrimidines (see Chapter 3) we realised the possibility for cleavage of the aromatic pyrimidine ring (Figure 4.3.1).

![Figure 4.3.1. Potential for pyrimidines to act as a guanidine precursor.](image)

The most challenging aspect of this proposed transformation would be the enhanced reactivity of compound 248 towards nucleophilic attack in comparison with 377 (Scheme 4.3.1). The reason for this enhanced reactivity is the extra substituent present on the nitrogen atom of 248 located in the pyrimidine ring. This alters the typical aromaticity associated with pyrimidine ring. The inability to form a cyclic six π electron speceis destabilises the system (Scheme 4.3.1). Position 248a has the potential to act as a conjugate addition acceptor while position 377a does not have the same reactivity.

![Scheme 4.3.1.](image)

Another example of reactivity that inspired confidence in our synthetic plan to cleave the pyrimidine ring is the Chichibabin reaction (Scheme 4.3.2). This reaction, although
typically used for the amination of pyridines 378, has been applied to pyrimidines and related purines in a number of publications.222

Scheme 4.3.2.

The Chichibabin reaction involves the use of sodium amide in an ammonia solution at elevated temperatures to facilitate the amination of nitrogen heterocycles 379.21 Although the Chichibabin reaction requires remarkably harsh conditions it should be noted the ability of a nitrogen nucleophile to break the aromaticity of pyridine forming a Meisenheimer complex. As pyrimidine has less aromatic stabilisation than pyridine due to the presence of an extra nitrogen atom in its ring, it was believed that more facile conditions than those used in the Chichibabin reaction could be used to break aromaticity.

An additional reaction that involves the ring opening of nitrogen heterocycles is the Dimroth reaction (Scheme 4.3.3).222 When the ring nitrogen of 2-aminopyrimidine is substituted, there are two possible tautomeric forms, either an extracyclic amine 380 or an extracyclic imine 381. The imino tautomer would be more stable due to the lack of a positive charge on the ring nitrogen (Scheme 4.3.3). When exposed to water this highly reactive species will undergo nucleophilic attack by the water on the aromatic ring. This has the ability to break the aromaticity of the pyrimidine ring and open it forming an aldehyde functionality along with a guanidine. The nucleophilic guanidine can reclose the ring but it will preferentially do this by the attack of the unsubstituted nitrogen to the aldehyde. In a forward sense, this will lead to
the extracyclic amino functionality being substituted and a highly stabilised, aromatic pyrimidine core 382.

Scheme 4.3.3.

Coinciding with these findings a literature example that results in the ring opening of pyrimidine was discussed in Section 1.5.2. In this example, it was shown that the use of tosyl protected pyrimidines is critical for the success of a reaction to open the pyrimidine ring and result in subsequent rearrangement. The strongly electron withdrawing tosyl group facilitates the formation of an extracyclic imine 245; then, the pyrimidine ring can be opened using the nucleophilic nitrogen of dimethylamine (Scheme 4.3.4.).

Scheme 4.3.4.

Each of the above examples encouraged us to attempt the cleavage of 2-aminopyrimidine derivatives. Unfortunately, the task was not as straightforward as had been expected.
4.4. Initial cleavage attempts.

*N*-Phenyl-2-aminopyrimidine 353 was chosen as a substrate to begin our initial cleavage experimentation. Choosing conditions which had proved useful for Al-Mourabit,\textsuperscript{15b} we began with the use of hydroxylamine hydrochloride as a nucleophile in combination with a variety of solvent, base and temperature choices (Table 4.4.1, entries 1-8).

Discouragingly, no product was observed in any of the initial reaction conditions. As has previously been alluded to, the stability of our system was undoubtedly going to be our major hindrance in this reaction and it was thought to increase the temperature and choose a more polar solvent to try and facilitate reactivity (Scheme 4.4.1.).
Polar, aprotic solvents are known to often aid nucleophilic aromatic substitution (NAS) reactions and although this cleavage reaction does not adhere precisely to that type of reactivity it should have characteristics similar to NAS reactions. In particular, the formation of anionic Meisenheimer complexes (Scheme 4.4.1., 383) is known to be favoured by the use of polar, aprotic solvents. Initial attempts to cleave compound 353 are presented in Table 4.4.2.

Chapter 4

A synthesis of aryl guanidines.

It was with much delight that the first trace of product formation was detected using Mass spectroscopic analysis (Table 4.4.2, entries 1 – 3). Firstly a number of bases were investigated (Table 4.4.2, entries 4 – 7). However, even at a temperature of 140 °C, yields in excess of 40% could not be achieved (Table 4.4.2, entries 8 – 10). The polar nature of guanidines results in their arduous purification, therefore, yields were obtained by recovering the $N$-phenyl-2-aminopyrimidine 353 starting material. With these initial results we were unconvinced of the utility of this reaction due to the harsh conditions and the problems associated with the purification of the guanidine products. We therefore turned our attention to a number of other nucleophiles in the hope that the reaction conditions could be made more utilisable (Table 4.4.3).

$^a$353 (1 mmol), nucleophile (10 mmol), additive (10 mmol), solvent (10 mL). $^b$BRSM.

The use of propylamine as a replacement for hydroxylamine was in no way advantageous giving similar results to those previously observed (Table 4.4.3.; entry 1). Attempted utilisation of a sulfur nucleophile such as sodium ethanethiolate (Table 4.4.3, entry 2) had no effect on the pyrimidine system. Utilisation of the dimsyl anion (methyl sulfonyl carbanion, formed from the deprotonation of DMSO using NaH) also had no effect on the system (Table
4.4.3, entry 3). A quick screening of hydrogen peroxide in a variety of conditions acting as a nucleophile also did not give the desired product (Table 4.4.3, entries 4 - 6).

From our initial findings it was therefore apparent that the stability of the pyrimidine ring was not going to be susceptible to facile cleavage conditions. Thus, it was decided to investigate alteration of the pyrimidine ring to make it more vulnerable to cleavage conditions since it is known that, for example, incorporation of a nitro derivative at the 5 position of pyrimidine makes the ring susceptible to basic hydrolysis.\(^ {225} \)

4.5. Functionalisation of the pyrimidine ring.

We proposed to change the electronic properties of the pyrimidine ring by introducing separately both electron withdrawing or electron donating groups. Our first choice was to use 2-amino-4,6-dimethoxypyrimidine \(384\) as a pyrimidine derivative with extra electron density in the ring due to the presence of the two electron donating methoxy groups. It was intended that these groups would make the pyrimidine a more susceptible target for either acid or base hydrolysis (Scheme 4.5.1).

Scheme 4.5.1.

The commercial availability of 2-chloro-4,6-dimethoxypyrimidine \(385\) and 2-amino-4,6-dimethoxypyrimidine \(384\) made this route particularly appealing. To quickly access a functionalised derivative of \(385\), this was reacted with benzylamine \(110\) under basic conditions to generate \(386\) in high yield (Scheme 4.5.2). With \(N\)-benzyl-2-amino-4,6-dimethoxypyrimidine \(386\) synthesised we were then free to explore its potential to act as a guanidine precursor.
Scheme 4.5.2.

Before cleavage reactions were carried out in the laboratory, the $^1$H and $^{13}$C NMR spectra corresponding to 386 were analysed (Figure 4.5.1).

Figure 4.5.1. $^1$H and $^{13}$C NMR spectra corresponding to compound 386.
Scrutiny of the proton spectrum indicates the positioning of the single pyrimidine ring proton at 5.42 ppm. For an aromatic proton this is unusually far upfield and this would lead one to believe that the system does not have the same aromatic stabilisation seen in typical 2-aminopyrimidine derivatives. The analogous proton for an N-substituted 2-aminopyrimidine would be located typically at 6.70 – 6.80 ppm. Also of significant interest is the location of the methoxy substituted quaternary carbons of the pyrimidine ring. Their location at 174.2 ppm is more reminiscent of the carbonyl peak of an ester (ethyl acetate carbonyl peak 171.4 ppm) than that of a quaternary peak of an anisole (typically around 160.0 ppm).

These initial findings from our NMR spectroscopy analysis were encouraging. Thus, pyrimidine 386 was exposed to nucleophilic, acidic and basic conditions separately. The compound was unaffected by either base or nucleophile (Table 4.5.1. entries 1 and 2). However, in the presence of aqueous hydrochloric acid the pyrimidine backbone was cleaved resulting in guanidine hydrochloride salt formation (Table 4.5.1. entry 3). This was a most rewarding result after numerous, previously disheartening outcomes.

Table 4.5.1. Cleavage of \(N\)-benzyl-2-amino-4,6-dimethoxypyrimidine.\(^a\)

After several replications of this result it was decided that the synthesis of \(N\)-aryl-2-amino-4,6-dimethoxypyrimidines by means of Pd catalysed amination reaction was possible and that the cleavage of compounds of this type would generate our desired aryl guanidines. During a literature search, a single example showed the instability of dimethoxypyrimidines...
to acidic conditions. Moulard and coworkers reported the preparation of 1-(3-ethylsulfonylpyridin-2-yl)guanidine 388, as a side-product, when treating N-(3-ethylsulfonylpyridin-2-yl)-2-amino-4,6-dimethoxypyrimidine 389 with concentrated HCl (Scheme 4.5.3). This publication further showed the potential for 2-amino-4,6-dimethoxypyrimidine derivatives to act as guanidine precursors.

**Scheme 4.5.3.**

![Scheme 4.5.3](image)

**4.6. Pd-catalysed coupling of aryl bromides with 2-amino-4,6-dimethoxypyrimidine and subsequent cleavage to afford aryl guanidines.**

From our previous experience utilising Buchwald-Hartwig amination chemistry (see Chapter 3, Section 3.2.1), we realised that the most efficient method to synthesise N-aryl-2-amino-4,6-dimethoxypyrimidines would be to couple aryl bromides with 2-aminopyrimidine-4,6-dimethoxypyrimidine 384. Optimisation of the coupling of bromobenzene 356 with 384 was therefore initially carried out. From our previous findings we decided it was necessary first to test each of the different ligands that we had examined in Section 3.2.1. as they had afforded the most dramatic change in yields (Table 4.6.1, entries 1 - 5). Different bases and solvents, known to be particularly effective in promoting this type of transformation, were also examined (Table 4.6.1, entries 6 & 7).

Pd$_2$(dba)$_3$ (2 mol%), ligand (3 mol%), NaO/-Bu (1.5 mmol), toluene (1.5 mL per mmol of aryl halide), 95 °C, 8-12 h.  

Compound 356 was readily coupled with pyrimidine 384 under Pd-catalysed conditions to afford the desired product 391 in 96% yield (Table 4.6.1, entry 5). This result was also replicable on a multi-gram scale (Table 4.6.1, entry 8). Then, we applied these optimised conditions to a wide range of aryl bromides incorporating electron donating (Table 4.6.2, entries 1 – 3), halogen (Table 4.6.2, entries 4 – 6), electron withdrawing (Table 4.6.2, entries 7 – 11) and sterically cumbersome (Table 4.6.2, entry 12) substituents.

\textsuperscript{a}384 (1.5 mmol), NaO\textsubscript{t}-Bu (1.5 mmol), aryl halide (1 mmol), Pd\textsubscript{2}(dba)\textsubscript{3} (2 mol %), Xantphos (3 mol %), toluene (1.5 mL/mm mol aryl halide), 12 h. 95 °C. \textsuperscript{b}K\textsubscript{3}PO\textsubscript{4} used as base.

The yields of isolated product range from 50 - 97%, but, in general, were very good to excellent. The slight downfall in yields appears for the aryl bromides with strongly electron withdrawing substituents (Table 4.6.2, entries 7-11). As previously discussed in Section 3.2.1, the use of NaO\textsubscript{t}-Bu is incompatible with electron withdrawing substituents located on the aryl bromide. We noted that K\textsubscript{3}PO\textsubscript{4} was again the base of choice for this reaction. We have discussed the potential for two catalytic cycles through which the Buchwald-Hartwig reaction is thought to proceed (Figure 3.2.1.3, Chapter 3). Potentially, the presence of strongly electron withdrawing groups would favour the pathway involving initial interaction of NaO\textsubscript{t}-Bu with the Pd centre (Figure 3.2.1.3, green pathway), which may be unfavourable. Therefore, replacing the base with non-nucleophilic K\textsubscript{3}PO\textsubscript{4} allows the reaction to continue to go through the blue pathway and prevents the deleterious effects seemingly associated with
the green pathway (for a linear representation of the beginning of the catalytic cycle see Scheme 4.6.1).

Scheme 4.6.1.

For a discussion on the merits of using Xantphos 352 as a ligand for the coupling of 2-aminopyrimidine and its derivatives please see Section 3.2.1.

4.7. Cleavage of \( N \)-aryl-2-amino-4,6-dimethoxypyrimidines to yield aryl guanidines.

With our selection of pyrimidines in hand we turned our attention to the optimisation of the cleavage reaction previously discovered in Section 4.5. \( N \)-phenyl-2-amino-4,6-dimethoxypyrimidine 391 was exposed to a variety of acidic conditions over a range of temperatures (Table 4.7.1).

a384 (0.25 mmol), acid (5 mmol), additive (solution of acid prepared from 12N HCl with 1:1 additive/H2O). bThe reaction vessel was wrapped in aluminium foil and the condenser was attached with vacuum grease. c2 g scale. dIsolated yield.

Preliminary cleavage experiments gave moderate yields and this was presumably due to the poor solubility of the pyrimidine in a number of solvent conditions (Table 4.7.1, entries 1 – 8). A significant improvement was noted when acetic acid was used as a co-solvent ensuring that the starting material was fully soluble (Table 4.7.1, entry 9). A further improvement was observed when the reaction vessel was coated with aluminium foil and the attached reflux condenser was fitted with vacuum grease (Table 4.7.1, entries 10 - 11). Presumably, this acts to keep the reaction vessel temperature uniform throughout and ensures no change in the concentration of the reaction. Moreover, this reaction was gratifyingly replicable on a multi-gram scale (Table 4.7.1, entry 12).
The pyrimidine family previously synthesised was then exposed to the optimised cleavage conditions to afford a diverse family of aryl guanidines.

^a Isolated yields.

Yields for this reaction ranged from good to excellent with the exception of the p-nitro derivative which gave a meagre 46% yield. This result can be explained by the strong delocalisation of the anilino nitrogen atoms lone pair into the nitro derivatised phenyl ring which would impede the postulated mechanism for this reaction (Scheme 4.7.1). The hydrolysis of the nitrile groups located both *meta* and *para* on the phenyl ring to their
carboxylic acid counterparts was expected (Table 4.7.2, entries 7 & 8). When the hydrolysis of *ortho* nitrile compound 392i was attempted initial guanidine formation resulted in attack of the guanidine group on the adjacent nitrile group resulting in ring closure to form compound 394i. Similar reactivity has previously documented for the closure of guanidine on nitrile functionalities.\textsuperscript{226}

A possible mechanistic explanation of this cleavage reaction is proposed in Scheme 4.7.2. The pKa of the pyrimidine ring nitrogen of *N*-phenyl-2-amino-4,6-dimethoxypyrimidine has been estimated to be \( \sim 3 \)\textsuperscript{218} and, therefore, will be protonated in strongly acidic conditions. Protonation will most likely occur on the ring nitrogen due to the ability for delocalisation of the positive charge (Scheme 4.7.1, A), addition of a proton to the exocyclic nitrogen would not benefit from this same stabilisation (Scheme 4.7.1, B).

**Scheme 4.7.1.**

Protonation of the molecule 395 effectively lowers the aromaticity of the pyrimidine ring and makes 396 it more susceptible to nucleophilic attack from a water molecule. Delocalisation of the positive charge over the guanidine like moiety is also possible and this would further facilitate nucleophilic attack. After the attack of the water molecule (Scheme 4.7.2), proton transfer would afford intermediate 397. Favourable expulsion of the protonated guanidine component from the formation of an ester would generate 398. Enamine/imine tautomerisation of 398 would form an imine which, under these aqueous acidic conditions, would be hydrolysed to yield the desired guanidine containing compound 399 and dimethyl...
malonate 400. Compound 400 would then be hydrolysed to malonic acid which would decompose to give acetic acid and carbon dioxide thus ensuring no unwanted side products are formed.

Scheme 4.7.2.

With our synthetic methodology successfully developed for the cleavage of the pyrimidine ring system it seemed logical to extend this reaction to the preparation of N-alkyl guanidines. The commercial availability of 2-chloro-4,6-dimethoxypyrimidine 385 enabled the facile synthesis of a number of varying N-substituted 2-aminopyrimidines. A selection of amines was reacted with 385 in the presence of a base (triethylamine) while heating to reflux in iPrOH to produce our desired products. The pyrimidine system readily underwent nucleophilic aromatic substitution with both primary (Table 4.8.1. entries 1, 2, 3, 9) and secondary amines (Table 4.8.1. entries 4 - 8)

Our next challenge was to apply the cleavage reaction developed in Section 4.7 to the library of $N$-substituted 2-aminopyrimidines presented in Table 4.8.1. We began our investigations by utilising the conditions of 6M HCl in a combination of $H_2O$ and AcOH to cleave the pyrimidine ring of compound 386, which had previously proved to be very useful as a test (Table 4.8.2. entry 1). Full conversion of 386 into 387 was an encouraging result and we envisioned that more gentle conditions may be sufficient to hydrolyse this family of compounds and accordingly we optimised such conditions.

$^a$ Isolated yield

Initial attempts at cleavage with weakly acidic conditions (Table 4.8.2, entry 2) gave poor results while increasing the concentration of hydrochloric acid led to the optimal conditions of 4M HCl at 80 °C being obtained (Table 4.8.2, entries 3 and 4). It is thought that the use of milder conditions for the cleavage of alkyl derivatised aminopyrimidines in comparison with N-aryl 2-amino-4,6-dimethoxypyrimidines (4M HCl at 80 °C as opposed to 6M HCl at 100 °C) is due to the availability of the lone pair of the exocyclic nitrogen of compound 386. This availability would most likely enable donation of the lone pair into the aromatic system of the pyrimidine enabling facile protonation of one of the ring nitrogens subsequently leading to hydrolysis. In comparison, the lone pair of the exocyclic nitrogen of 391 could be equally delocalised into the phenyl ring, preventing facile protonation of the pyrimidine. Examination of the calculated $pK_{cal}$ values$^{218}$ of $N$-phenyl-2-amino-4,6-dimethoxypyrimidine 391 and of $N$-benzyl-2-amino-4,6-dimethoxy pyrimidine 386 indicate values of 3 and 4.2 respectively. This, although a calculated value, is a good indicator of the ease of protonation of the pyrimidine ring system in each of the two cases (Figure 4.8.1).
The optimised cleavage reaction was then applied to the synthesised pyrimidines shown in Table 4.9.1. Pleasingly, the conversion from pyrimidine into guanidine was afforded under these conditions in good to excellent yields (Table 4.8.3, entries 1, 3, 4, 5, 6, 7). The poor yields associated with entry 2 was due to the formation of exceptionally polar products which proved to be challenging in the purification step.

Unsurprisingly, exposure of 2-(1H-imidazol-1-yl)-4,6-dimethoxypyrimidine 402g (Table 4.8.3, entry 7) to the acidic cleavage conditions resulted in favourable protonation of the imidazole moiety which subsequently led to carbon-nitrogen bond cleavage presumably through nucleophilic attack of water to the pyrimidine ring. The indole ring system of 402h also proved susceptible to these conditions leading to the formation of a complex mixture of products which could not be characterised (Table 4.8.3, entry 9).

To further explore the synthetic utility of the developed cleavage reaction and for seeing a potential application of the 2-amino-4,6-dimethoxypyrimidine group as a precursor of guanidine groups in amino acid synthesis, it was decided to investigate the ability to utilise this guanidine precursor in conjunction with amino protecting groups such as Cbz-, Piv- and...
Fmoc-. These groups were chosen as they are common in the preparation of amino acids and because they could potentially be used with 2-amino-4,6-dimethoxypyrimidine group in an ‘orthogonal’ manner. Thus, ethylenediamine (in excess) was reacted with compound 385 to form 402c. This was in turn reacted with the requisite protecting group precursor to afford the desired compounds 404a-c (for a more detailed account please see Chapter 8). Each of these protected substrates was then exposed to the optimised cleavage conditions with the hope of obtaining the corresponding guanidine and that the other protecting group would be retained. In the case of both the Cbz- protected analogue 404a and the Piv- protected compound 404b, the two protecting groups were both removed to afford deprotected guanidine 403c (Table 4.8.4, entry 1 – 2). However, as was expected, Fmoc- protected 404c, underwent ring cleavage but retained the Fmoc- protecting group which is known to be typically removed under basic conditions (Table 4.8.4, entry 3).229 This further shows the utility of this pyrimidine protecting group.

<sup>a</sup> Isolated yield.

4.9. Application of the developed cleavage reaction to the synthesis of α<sub>2</sub>-adrenoceptor antagonists.

The role of guanidine containing compounds as α<sub>2</sub>-adrenoceptor antagonists was introduced in Section 3.1. From previous studies in the group, two compounds (Figure 4.9.1, 340 and 341) had been discovered showing particularly good affinity and antagonism for the α<sub>2</sub>-adrenoceptor as well as antidepressant activity in animal models. 145,230-232
From these two structures a new compound was designed containing structural similarities to both. This indoline scaffold incorporates both the sterically demanding cyclohexyl ring of 340 along with the increased hydrogen bonding abilities of 341. Previous synthetic studies in the group\(^{33}\) involved a cumbersome approach towards the preparation of 406 (Scheme 4.9.1).

The ability of the newly developed cleavage reaction to access guanidine 406 quickly and efficiently was evident. The protection of 5-bromoindoline 410 with pivaloyl chloride generated 411, which in turn was successfully coupled with 2-amino-4,6-
dimethoxypyrimidine 384 utilising the conditions shown in Table 4.6.1. to afford compound 412 in an adequate yield (63%). Then, the acid promoted deprotection of the pivaloyl group and concomitant cleavage of the pyrimidine ring yielded the corresponding target compound 406 in excellent yield (89%, Scheme 4.9.2).

Furthermore, compound 406 was evaluated for biological activity by measuring its affinity for the $\alpha_2$-adrenoceptor ($pK_i$ value). The $pK_i$ (the log of the binding constant for a particular drug) is a measure of how effectively a compound binds to a given receptor and this value is determined by the ability of the drug candidate to displace a compound with known high affinity for the receptor. The $\alpha_2$-adrenoceptor $pK_i$ values of antagonists 340 and 341 are 7.11 and 6.58, respectively.

Unfortunately, in the case of compound 406 a relatively low $pK_i$ value of 4.89 was obtained and such a result did not encourage further investigations into whether or not this compound acts as an $\alpha_2$-adrenoceptor antagonist as its binding affinity is too low for it ever to be an effective drug candidate (Figure 4.9.2).
Figure 4.9.2. Determined $pK_i$ value for compound 406 (Courtesy of Michela McMullan).

Despite the disappointing biological results obtained for compound 406 its facile synthetic route shows the utility of the developed cleavage reaction.
Chapter 5  Spiro guanidine aminals

5. Spiro guanidine aminals.

The prevalence of the guanidine group in natural products has been highlighted in the Introduction section of this thesis. In this Chapter, selected examples of the synthesis of spiro guanidine aminal 19 are presented (Figure 5.1.).

Figure 5.1. The spiro guanidine aminal 19 functionality.

5.1. Spiro guanidine aminals in natural products and selected syntheses of this motif.

The presence of a spiro guanidine aminal moiety 19 is prevalent in natural product chemistry.\textsuperscript{36} In particular, the pyrrole-2-aminoimidazole family of marine natural products often incorporate this interesting motif. These natural products predominantly originate from the \textit{Agelasidae}, \textit{Halichondridae} and \textit{Axinellidae} families of marine sponges.\textsuperscript{36} Looking at the proposed biosynthesis of such natural products, the origin of this molecular structure is evident. This molecular feature stems from central precursor clathrodin 413 and brominated analogue oridin 414 (Figure 5.1.1).

Figure 5.1.1. Structures of clathrodin (413, R=H) and oridin (414, R=Br).

Biosynthetic pathways proposed by Kitagawa\textsuperscript{234} and Braeckman\textsuperscript{235} propose the selective guanidylation of ornithine 415 to form intermediate 416 which upon cyclisation and
oxidation could generate the necessary imidazole precursor 417 (Figure 5.1.2). When combined with 418, the oxidised pyrrole analogue of proline 203, clathrodin 413 could be formed.

Figure 5.1.2. Proposed biosynthesis of clathrodin 413.

The formation of the spiro guanidine aminal fragment is then proposed to occur via an oxidative polycyclisation reaction (Figure 5.1.3). This chemical behaviour of imidazoles is typically seen in the biosynthesis of spiro guanidine aminals.

Figure 5.1.3. Oxidative cyclisation of dihydroooridin 419 to form dibromophakellin 23.
In an effort to investigate the mechanistic feasibility of this reaction Büchi and co-workers (1982) designed a laboratory experiment to mimic this reactivity (Scheme 5.1.1). As desired, exposure of 419 to bromine and, then, basic conditions, generated 23. The reactivity displayed here reinforced the proposed biosynthetic pathway. This reactivity was again displayed in a synthesis of 23 by Horne in 2002.

Scheme 5.1.1.

In an effort to mimic the oxidative polycyclic cyclisation that occurs in the biosynthesis of 23 (Figure 5.1.3), Feldman and co-workers (2007/2008) implemented a novel synthetic route to facilitate the formation of aminal 420. Oxidative cyclisation of phenylthiolated dihydrooridine derivative 421 triggered by a Pummerer reaction generated late stage intermediate 420 which could subsequently be converted into 23 (Scheme 5.1.2).

Scheme 5.1.2.
In another aminal forming reaction, Molina et al.\textsuperscript{239} designed a highly effective oxidative spirocyclisation of thiohydantoin 422 to generate phakellin analogue 423 (Scheme 3.6.1.4.). This step is facilitated by the use of DDQ (DDQ = 2,3-dichloro-5,6-dicyano-1,4-benzoquinone).

Scheme 5.1.3.

\begin{center}
\includegraphics[width=0.8\textwidth]{scheme513.png}
\end{center}

Al-Mourabit et al. have effectively synthesised numerous pyrrole imidazole alkaloids by a variety of intriguing methods.\textsuperscript{153b} Their use of 2-aminopyrimidine 346 as a guanidine surrogate is of particular interest. Addition of 346 to conjugated enecarbamate 248 facilitates the aminal framework 249 in a concise and effective manner (Scheme 5.1.4).

Scheme 5.1.4.

\begin{center}
\includegraphics[width=0.8\textwidth]{scheme514.png}
\end{center}

Since 2008 a number of reports detail late stage guanidine introduction and cyclisation during the synthesis of pyrrole–imidazole alkaloids. Of particular note are the publications from Romo\textsuperscript{240} and separately from Tepe.\textsuperscript{241} Romo uses a potent C(sp\textsuperscript{3})-H activation reaction to furnish protected dibromophakellin 424 and form the desired aminal moiety (Scheme 5.1.5, route a), while Tepe utilises NBS olefin activation to facilitate guanidine addition across the olefin 425 to form dibromophakellin precursor 426 (Scheme 5.1.5, route b).
In an elegant study towards another spirocyclic guanidine aminal natural product, palau’amine 21, Overman and co-workers (1997) designed a cycloaddition reaction to form the carbon-nitrogen bonds of aminal 427. When exposed to acetic acid at 70 °C, compound 428 and thiosemicarbazide underwent [3+2] dipolar cycloaddition and subsequent acylation to deliver tetracycle 427 in excellent yield (Scheme 5.1.2). This method portrays an ingenious approach for the rapid generation of structural complexity.
5.2. $\alpha_2$-Adrenoceptor agonist dibromophakellin.

The discovery of dibromophakellin 23 as an agonist of the $\alpha_2$-adrenoceptor, stimulated the idea in Rozas’ group that structural modifications to the spiro guanidine aminal backbone may provoke an antagonistic effect. As part of the medicinal chemistry program in Rozas’ group, new and effective structural motifs are constantly required to investigate agonism, antagonism and receptor affinity of new molecules at the $\alpha_2$-adrenoceptor. In an attempt to provide rapid access to this architecture, a novel cascade cyclisation reaction was envisaged (Figure 5.2.1).

![Figure 5.2.1. Retrosynthetic analysis of spiro guanidine aminal derivative 429.](image)

The aim for this route was to devise a highly efficient synthesis which could afford large quantities of the required aminal 19 that could be further derivatised to produce a library of guanidine containing compounds to be investigated for biological activity.

5.3. First generation synthetic route.

First, we planned to prepare an open ring variation of dibromophakellin 23 (Figure 5.3.1). This variation was thought to play a significant role in agonist/antagonist differentiation. Previous studies have showcased the substantial effects minute conformational changes can exhibit on the biological role of the ligand.\textsuperscript{145,190,230-232}
Figure 5.3.1. Desired structural change of 23.

Retrosynthetic analysis of 431 led to the linear molecule 432 (Fig. 5.3.2), which was proposed to be rapidly generated through known synthetic procedures.

Figure 5.3.2. Retrosynthetic analysis of 431.

This retrosynthesis was centred on a late stage amide ketone condensation of compound 432 which should be directly followed by guanidine attack on the highly electrophilic carbon to form spiro compound 431. Precedence for amide condensation has previously been observed utilising formic acid\(^*\) and it was expected that a range of both Bronsted and Lewis acids would be able to ameliorate this transformation. Under mildly acidic conditions it was imagined that iminium cation formation would coax guanidine attack (Scheme 5.3.1).
Our synthetic endeavour began with pyrrole 433 which was benzyl protected. Prior distillation of 433 was necessary to afford 434 in good yield which could advantageously be purified using vacuum distillation. Alkylation at the nitrogen was achieved by the use of sodium hydroxide to generate the sodium salt of pyrrole, an ionic species which favours reaction at nitrogen as opposed to ring substitution. Exposure of 434 to trichloroacetyl chloride furnished the trichloroacetate appendage at the nucleophilic 2-position of the pyrrole ring in good yield generating 435. The use of 4-amino-1-butanol 436 to attack the trichloroacetate moiety began the formation of the linear aspect of the molecule, yielding alcohol 437 as a brown solid in acceptable yields (Scheme 5.3.2).

Generation of the α-guanidino ketone featured in 432 was planned through a series of known chemical transformations including oxidation of alcohol 437 to its aldehyde analogue. This would be followed by a Henry reaction, secondary alcohol oxidation, nitro reduction and guanidylation (Scheme 5.3.3).
With alcohol $437$ in hand, a number of oxidising conditions were investigated (Table 5.3.1, entries 1-5). Even though initial oxidation reactions proved to be problematic it was possible to generate the desired aldehyde as indicated by TLC (Figure 5.3.3, plate A). Attempts to purify aldehyde $438$ by column chromatography led to a multitude of impurities. Replication of this reaction also led to a number of varying results.

Table 5.3.1. Conditions attempted for oxidation of primary alcohols $437$ and $439$.a

a BRSM. For a full description of experimental conditions see Chapter 8.
It was thought that the presence of the highly reactive pyrrole moiety might be responsible for the formation of side products as it is known to be sensitive to oxidising conditions. In an effort to harness the internal reactivity of this molecule the brominated analogue of alcohol 439 was synthesised (Scheme 5.3.4). Upon exposure to oxidative conditions (Table 5.3.1. entries 6 and 7), this strategy had no effect on the uncontrollable nature of this reaction. After extensive attempts at purification involving differing column chromatography conditions it was decided that use of the crude aldehyde may be beneficial.

Scheme 5.3.4.

The next step in the synthesis required a Henry reaction to introduce the alkyl nitro moiety. Exposure of crude aldehyde to Henry conditions generated nitro product 441 along with a
number of impurities (Fig 5.3.3, plate B). However, after purification 441 could be easily isolated as a yellow oil (Scheme 5.3.5) in an acceptable yield over the two steps (48%). This step became the initial bottleneck in our endeavour towards 432 as scale up complications were a major hindrance, and the realisation that another oxidising step was going to be required seemed daunting.

Scheme 5.3.5.

Therefore, attempts to reduce the nitro moiety to an aliphatic amine became the primary focus of our attention. A number of reducing metal conditions were all efficient in this synthetic step; however, the exceptional polarity of the amino alcohol 442 produced had not been anticipated (Table 5.3.2; entries 1-3) and led to purification issues.

The most efficient reduction process was found to be the use of hydrogenative conditions in the presence of catalytic Pd/C (Table 5.3.2, entry 4). Gratifyingly, this afforded amino alcohol 442 without the need for extensive purification.

Following this successful reduction our focus was guided towards the guanidylation of 442. A number of guanidylating conditions were investigated for this transformation (Table 5.3.3, entries 1 - 7), with \(N,N\)'-bis-Boc-thiourea 128 proving to be the most effective (Table 5.3.3, entry 1).

This reaction worked efficiently when HgCl₂ was used as the Lewis acidic promoter to stimulate desulfurisation. Analogous experiments either without Lewis acid (Table 5.3.3, entries 3 and 4) or with CuCl₂ as an alternative Lewis acid (Table 5.3.3, entry 5) gave inferior results.

Oxidation of 443 to ketone 444 proved slightly less problematic than initially expected and gave additional insight into the problematic initial oxidation reaction (Scheme 5.3.6).

![Scheme 5.3.6.](image)

The relative ease of oxidation in this synthetic step suggests that the aldehyde present in product 438 (Table 5.3.1) was the source of problems in the first oxidation step. Potentially, the aldehyde was being attacked by the nucleophilic amide or pyrrole functionalities.

In this reaction, freshly prepared Dess-Martin periodinane (DMP, Scheme 5.3.7) proved to be an essential reagent for the oxidation of secondary alcohol 443 to α-guanidino ketone 444 (Scheme 5.3.6).

![Scheme 5.3.7.](image)
With our desired cyclisation precursor in hand we shifted our focus to transform \( \text{444} \) into the desired final compound \( \text{431} \). With the hope that formic acid mediated condensation between an amide and a ketone could potentially induce our first ring closure, we attempted the conditions described by Nielsen and co-workers.\(^\text{243} \) In their paper, they describe the condensation of an amide onto a ketone to form an acyl iminium cation, which, when in the presence of a suitable nucleophile, can be captured (Scheme 5.3.8).

\[ \text{Scheme 5.3.8.} \]

Initial experimentation using formic acid to achieve ring closure was unsuccessful. Upon exposure to formic acid at elevated temperatures Boc deprotection occurred leaving a highly polar guanidine product \( \text{445} \) (Scheme 5.3.8, as determined by TLC analysis).

\[ \text{Scheme 5.3.8.} \]

Following this result, it was realised that the deprotected guanidine \( \text{445} \) should still be a suitable precursor for the cyclisation reaction to occur. Compound \( \text{444} \) was therefore exposed to formic acid at elevated temperatures of 80 °C for 11 h. However, this generated the undesired natural product dihydroclathrodin \( \text{446} \) in its benzyl protected form (Scheme 5.3.9). The guanidinium cation was proving to be more nucleophilic than the amide functionality and preferentially reacting with the ketone.
Scheme 5.3.9.

Although this compound is a precursor for dibromophakellin 23 it did not afford our desired aminal guanidine scaffold and, therefore, another synthetic route had to be devised.

5.4. Second generation synthetic route.

The condensation of a primary amine with a ketone is a ubiquitous reaction in chemistry and was therefore thought to be a more facile route towards our planned bicycle (Figure 5.4.1).

Figure 5.4.1. Second generation retrosynthesis of 447.

This synthetic route would be mostly analogous to the first generation synthesis except for the late stage installation of the amide functionality. It was perceived that this would have the potential to be a more convergent route towards functionalised aminal-guanidines.

To synthesise guanidine 447 it was thought necessary to protect the primary amine of compound 448, which upon subsequent deprotection would facilitate ring closure. Previous
literature for phthalimide deprotection with ensuing ring closure supported the choice of phthalic anhydride 449 as a protecting group (Scheme 5.4.1).  

Scheme 5.4.1.

Hence, our forward synthetic route began with phthalimide protection of 4-aminobutan-1-ol 436 to afford primary alcohol 450. This step gave high yields and required no column chromatography. Ensuring the use of a Dean-Stark apparatus was essential for obtaining satisfactory results (Scheme 5.4.2).

Scheme 5.4.2.

Without the presence of any other nucleophilic functionality on alcohol 450 oxidation was an unproblematic step. Upon exposure to IBX, DMP or Swern oxidising conditions aldehyde 451 could be generated in high yields (Table 5.4.1. entries 1 - 3) and on a multi-gram scale (Table 5.4.1. entries 4 and 5).

After obtaining aldehyde 451, a Henry reaction was performed to generate nitro alcohol 452 in good yield (Table 5.4.2). Analogous reaction conditions were used to that in our first synthetic route which had always proven to be satisfactory. The decision to initially investigate the reduction of nitro 452 to generate amine 453 was made and a wide variety of conditions were analysed as outlined in Table 5.4.2. entries 1 – 3. It was found that Pd/C catalysed hydrogenation was the most effective reductive agent due to the facile work up required.
Table 5.4.2. Henry reaction and conditions for reduction of nitro derivative 452.\textsuperscript{a}

For a full description of experimental conditions see Chapter 8. BRSM

Contrary to our previous synthetic route, oxidation of nitro alcohol 452 was also attempted at this stage. The use of Dess-Martin periodinane was crucial in the effective oxidation of 452 to yield \( \alpha \)-nitro ketone 454 in satisfactory yield with no column chromatography required (Scheme 5.4.3). Dichloromethane was essential as a TLC eluent for this reaction as combinations of typical solvents (ethyl acetate, hexane, diethyl ether) showed no polarity difference between starting alcohol 452 and ketone product 454.

Scheme 5.4.3.

Reduction of the \( \alpha \)-nitro ketone 454 proved somewhat problematic since it appeared to occur (as per TLC) using reducing metal conditions but no notable product was detectable. Hydrogenative conditions previously exploited in our reduction of nitro compounds proved completely unsuccessful for the reduction of 454. After a number of dead-ends were encountered (Table 5.4.3. entries 1 - 3), hydrogenation in acidic conditions under 3 atm. of
hydrogen generated the required amine 455 as the hydrochloride salt (Table 5.4.3. entry 4). Much to our delight, amine 455 could be easily purified without the use of reverse phase column chromatography by simple trituration with diethyl ether.

\(^a\)For a full description of experimental conditions see Chapter 8.

In the case of \(\alpha\)-amino ketone 455 the use of \(N,N'\)-bis-Boc-thiourea 128 proved to be the most efficient method of guanidylation furnishing the desired molecule 456 in 68% yield.
Similarly, the guanidylation of amino alcohol 453 proved to be proficient utilising thiourea derivative 128 affording protected guanidine 457. Oxidation of the secondary alcohol 457 could then be easily facilitated using DMP (Scheme 5.4.5).

With cyclisation precursor 456 now in hand our attention moved to deprotection of the phthalimide group to attempt concurrent ring closures. A literature precedent utilises hydrazine as an effective means of deprotection.\(^{247}\) During the total synthesis of (+)-perophoramidine Wang and co-workers published a beautiful cascade reaction initiated by the hydrazine mediated deprotection of phthalimide.\(^{247}\) Initial deprotection of compound 458 generates a free amine 459 which attacks the oxindole amide in its immediate environment (Scheme 5.4.6, step 1) as opposed to the imine, preferentially forming a five membered ring. The expelled aniline (Scheme 5.4.6, step 2) can then attack the electrophilic imine (Scheme 5.4.6, step 3) forming the desired product 460.
With this highly promising reactivity being found, we tried to replicate their cyclisation success on our molecule 456. Cyclisation precursor 456 was exposed to a number of deprotecting conditions, initially with little success (Table 5.4.5, entries 1 and 2).

<sup>a</sup> N<sub>2</sub>H<sub>4</sub> (1M in THF solution). TCACl – Trichloroacetylchloride. <sup>b</sup> Yield of compound 461.

The first breakthrough came when the temperature was lowered to room temperature and then to 0 °C (Table 5.4.5, entries 3 and 4) which resulted in the formation of imine 461 which was predicted as an intermediate in this reaction pathway. Further improvements were obtained upon the utilisation of dry N<sub>2</sub>H<sub>4</sub> as a solution in THF (Table 5.4.5, entries 5 and 6). The absence of water in this reaction is of obvious benefit for imine formation with initial wet conditions affording poor results. This imine 461 was isolated and characterised. To facilitate the formation of the desired aminal product 462 the reaction was carried out (Table 5.4.5, entry 6) and upon complete formation of the intermediate imine 461 (TLC analysis), trichloroacetylchloride and NEt<sub>3</sub> were added (Table 5.4.5, entry 7) to generate guanidine aminal 462 in satisfactory yield (54%). This was a hugely rewarding result as a new cyclisation reaction for the formation of guanidine aminals has been developed also incorporating the trichloroacetate group which can potentially undergo further synthetic
transformations to lead to a library of spirocyclic compounds. In conclusion, \( N \)-benzyl dihydrocloathroin 446 has been synthesised serendipitously and a method for the formation of spirocyclic guanidine aminals has been discovered and its conditions optimised.
6. Investigations into the synthesis of araiosamines A-D.

Recently the araiosamine family of natural products have been isolated from a marine sponge of the family *Clathria Araiosa* (Figure 6.1). The specimen was obtained from the island nation of Vanuatu in the South Pacific ocean. Initial investigations suggested a heavily nitorogenated and halogenated family of compounds, with detailed NMR spectroscopy analysis leading to the assignment of the araiosamines A-D as shown in Figure 6.2. Indole functionalities and cyclic guanidines are ubiquitous in natural products isolated from marine sponges. However, it is incredibly rare for a trimeric indole compound to be isolated even though there is quite a large precedence for dimeric indole natural products. The presence of this trimeric core along with the two cyclic guanidine functionalities makes this family an incredibly interesting target for total synthesis.

![Figure 6.1. Araiosamines A-D.](image)

The proposed biosynthesis of the araiosamines is shown in Figure 6.2. A trimerisation between three guanidine enamines 463 (step - a) is proposed to occur, generating intermediate 464. This acyclic compound may then be able to undergo cyclisation from guanidine nitrogen 1 onto the imine functionality 2 forming the desired six membered moiety 465 present in araiosamine C (step - b). Subsequent expulsion of exocyclic guanidine 4 by
means of iminium formation from donation of electrons from the ring nitrogen 3 might facilitate a further cyclisation to occur from the other exocyclic guanidine 5 (step - c) forming intermediate 466. This would relieve the highly electrophilic iminium of its positive charge. Intermediate 467 can also be formed from compound 465 by a similar pathway. Oxidation of the benzylic position 6 could then result in the final ring closure (step - d). From intermediate 467 a number of outcomes can also occur to yield the other members of the araiosamine family.

![Diagram of proposed biosynthetic pathway of the araiosamine family.](image)

**Figure 6.2.** Proposed biosynthetic pathway of the araiosamine family. R = 6-Bromoindole, R¹ = amidine, omitted for clarity.

The initial synthetic plan focused on the idea that tautomeric forms of indole 468 would include guanidine enamine 469 under appropriate conditions (Figure 6.1.1) as has been proposed in the suggested biosynthetic pathway (Figure 6.2). In a biomimetic reaction, guanidine 469 would ideally be able to trimerise affording the desired natural products.

With this in mind, a synthesis of indole 468 was proposed using methodology previously utilised in the Baran laboratory for the synthesis of the stephacidins.248 Tryptophan derivatives 470 exposed to PhNO and ZrCl₄ generate tryptophan enamine derivatives 471 (Scheme 6.1.1). Nitrosobenzene (PhNO) is thought to be activated at the nitrogen in the presence of Lewis acids facilitating nucleophilic attack on oxygen. O-linked intermediate 472 might then immediately fragment to imine 473 and phenylhydroxylamine. Rapid interconversion to enamide 471 yields the desired compound. It was envisioned that intramolecular trapping of conjugated imine 474 by a guanidine nucleophile would result in the desired indole-guanidine structure.

![Figure 6.1.1. Tautomeric forms of indole 468 and potential for trimerisation.](image-url)
Exposure of guanidine indole 475 to analogous conditions resulted in complete degradation of starting material (Scheme 6.1.2). Potentially, the Lewis acidic conditions were too harsh for the Boc- protecting groups as had been demonstrated previously.\textsuperscript{249} With such a poor result it was thought best to explore alternatives for the preparation of indole 468.

Oxidative indole – enolate coupling is a proven method for the formation of C-C bonds between the 3 position of indole and an enolate.\textsuperscript{250} Exposure of both to base and an oxidising agent facilitates a radical type mechanism as outlined in Figure 6.1.2. Encouraged that this reactivity should facilitate rapid assembly of compound 468 it was decided to use commercially available creatinine 476 as a guanidine surrogate.
Boc-protected creatinine 477 was synthesised by a literature procedure and then exposed to oxidative coupling conditions with indole 478 (Scheme 6.1.3). Initial deprotonation of both 477 and 478 using LiHMDS (3.5 eq.) generated the anionic equivalents at -78 °C which upon exposure to copper(II)2-ethylhexanoate as an oxidising agent initiated reactivity. After 2 hours two products (one major, one minor) appeared to be formed (as indicated by TLC). Purification of the reaction mixture and NMR spectroscopic analysis indicated the coupling of two equivalents of indole to protected creatinine 477 resulting in highly functionalised creatinine 479. Efforts to synthesise desired mono-indole containing compound 480 were fruitless. The changing of equivalents of base, temperature or time individually either led to 479 or to no significant products.
It is thought that the over-reactivity of this species is due to the aromatic nature of intermediate 481 which could be formed and would be highly susceptible to further reaction (Scheme 6.1.4).

Following this dead-end, a more rewarding line of enquiry was investigated. Thus, tryptamine 482 was Boc-protected resulting in compound 483 and then exposed to DDQ to generate a benzylic carbocation as described by Feldman et al.\textsuperscript{252} which can be captured by an azide nucleophile to afford azide 484. Subsequent Staudinger reduction and acidic workup, generated diamine 485.\textsuperscript{253} Gratifyingly, exposure of 485 to CNBr formed the target guanidine compound 468 (Scheme 6.1.5).
Then, a variety of conditions were investigated for the self–trimerisation of 468 (Table 6.1.1, entries 1 - 4); however, no experiments yielded any desired products. Decomposition of 468 or recovery of 468 were the only two outcomes for these reactions.

Table 6.1.1. Investigations into trimerisation reaction of indole monomer 468.

6.2. Synthesis of indole 486.

Further retrosynthetic analysis of the araiosamine family generated indole 486 as a desired target (Figure 6.2.1). It was envisioned that upon attainment of 486 further functionalisation would be possible. Michael addition onto the conjugated benzylic position (Figure 6.2.1, -a) of 487 by an appropriate nucleophile and functionalization of the imidazole moiety (Figure 6.2.1, -b) could lead to an advanced intermediate towards the synthesis of the araiosamines.
To enable rapid production of 486, Boc-protected creatinine 477 was used as a readily available guanidine containing heterocycle. After preliminary experimentation it was discovered that piperazine assisted Knoevenagel condensation between indole-3-carboxaldehyde 488 and creatinine 477 generated intermediate 489 as an intensely yellow solid in very good yield (Scheme 6.2.1, 80%).

Initial experiments investigated the reactivity of the conjugated benzylic position of 489 (Figure 6.2.1, -a) towards nucleophilic attack. A variety of carbon nucleophiles were investigated for their potential to add to Michael acceptor 489. Acetylacetone 490 is an example of a carbon nucleophile which have been proven to be effective in Michael addition reactions under a myriad of conditions. The use of 489 in conjunction with different additives (Table 6.2.1, entries 1-3) gave no desired product and 489 was recoverable in all instances. Meldrum’s acid 491 was used as a more activated carbon nucleophile; however, as it was experienced with 490, no reactivity was observed.

Accepting the lack of reactivity of the benzylic position towards nucleophilic attack it was decided to explore the creatinine ring as a moiety for further functionalisation. Reduction of
the conjugated amide could afford a hemi-aminal, a reactive synthetic handle which could hopefully be manipulated. Due to its conjugated nature, 489 was initially exposed to Luche reducing conditions\textsuperscript{255} (Table 6.2.1, entry 4); however, no reactivity was noted. Further exposure to a variety of reducing agents (Table 6.2.1, entries 5-8) proved unfruitful and in all cases no products were formed and starting material 489 was recovered.

* RSM – recovered starting material, no desired products observed.

The lack of reactivity was due to the highly conjugated nature of 489 which prevented typical reactivity of this type of Michael acceptor to occur (Figure 6.2.2). Tautomeration between 489, 492 and 493 leads to an unusual stability and even in harsh reducing conditions (Table 6.2.1, entry 8) no products are formed. Assuming tautomeric form 492, sodium cyanoborohydride
was tested as a reducing agent (Table 6.2.1, entry 7). As expected from this incredibly stable molecule no reaction occurred.

Figure 6.2.2. Conjugated nature of 489.

Due to the inherent stability of indole 489 it was decided to abandon this line of investigation.

6.3. Enamide trimerisation.

During initial investigations into trimerisation reactions a beautiful paper by Terada and co-workers caught our attention. This paper describes a chiral phosphoric acid catalysed azaene type reaction to generate highly functionalised piperidines. In this reaction, two equivalents of enamide 494 are reacted with imine 495 in the presence of a chiral phosphoric acid 496 to initiate enamide addition to the imine (Scheme 6.3.1). This is followed by another equivalent of enamide 494 adding to the newly formed imine 497. This reactivity can then be terminated preventing polymerisation by an intramolecular attack of nitrogen on terminal imine 498 resulting in the formation of highly functionalised piperidine 499.
The synthetic utility of this procedure was obvious and appealing. It was thought that, by incorporating analogous indole-containing imine 500 and enamide functionalities 501, a highly derivatised piperidine core 502 could be synthesised containing the requisite three indole moieties (Scheme 6.3.2).

The synthesis of indole imine 500 was investigated. Carboxylic acid 503 was exposed to reductive conditions (LiAlH₄, THF) to generate alcohol 504 which it was hoped could be oxidised to furnish aldehyde 505. The synthesis of intermediate 505 however proved to be a challenging task due to its characteristic reactivity (Figure 6.3.1).
Scheme 6.3.3.

Under oxidising conditions (iodoxybenzoic acid – IBX), 505 could cleanly and quantitatively be formed as indicated by TLC; however, upon attempted isolation polymerisation occurred as indicated by NMR spectroscopy. After exhaustive attempts to obtain aldehyde 505, it could not be isolated or characterised and therefore it was decided to use 505 without purification.

Once the oxidation of alcohol 504 was deemed complete (TLC analysis) the reaction mixture was diluted with MeCN and filtered through a plug of Celite®. The resulting solution was then concentrated by rotary evaporation to give a roughly 1M solution of aldehyde 505 in MeCN. For instance, if the reaction scale was 1 mmol then the solution containing 505 was concentrated to ~1 mL of MeCN. The concentration dependence on the instability of 505 would indicate an intermolecular reactivity being the cause of our problems rather than an intramolecular problem (Figure 6.3.1). In order to form the imine it was decided to use sulfinamide 506 due to the extensive literature on the behaviour of sulfinimines. These
imines display unique reactivity and stereoselectivity due to the presence of the chiral electron withdrawing N-sulfinyl group. Condensation of sulfinamide 506 with aldehyde 505 was facilitated by Ti(Oi-Pr)₄ to yield imine 500. Over the two steps, an optimal yield of 12% was obtained providing an unstable imine (Scheme 6.3.3). The imine was also unstable under an inert atmosphere at -20 °C if left for longer than 12 h.

With the desired imine 500 tentatively in hand, we moved our attention to the formation of enamide 501. This synthetic route started with the N-acetylation of tryptophan methyl ester 507 to afford 508 followed by protection of the indole nitrogen with a tosyl protecting group which resulted in intermediate 509. Both steps proceeded efficiently and in good yield (Scheme 6.3.4). Hydrolysis of the ester afforded corresponding carboxylic acid 510 and, following this, a Pb(OAc)₄ mediated oxidative decarboxylation was employed to yield hemiaminal 511.

Scheme 6.3.4.

This mechanistically interesting step is proposed to proceed as shown in Scheme 6.3.5. Interaction of the carboxylic acid 510 with Pb(OAc)₄ facilitates the formation of N-acetoxy 512 which upon decarboxylation could generate imine 513. In the presence of the OAc anion it would be feasible to imagine addition to the electrophilic imine.
Hemi-aminal 511 was initially the focus of our attention since the prospect of nucleophilic attack and displacement of the acetoxy group by an appropriate substrate was appealing. However, we quickly learned that under basic conditions elimination of the acetoxy moiety ensued the formation of enamide 501 as primarily the cis isomer, which was presumably generated through a syn elimination pathway.

Now having access to both enamide 501 and imine 500 the trimerisation reaction conditions reported by Terada were investigated utilising phosphoric acid 514 as a catalyst. Upon exposure to this acidic environment only enamide 501 was recovered from the reaction (Scheme 6.3.6).

Realisation that trimerisation may be possible though the exposure of enamide 501 to suitably acidic conditions prompted further investigations in this area. Tautomerisation of 501 between its imine and enamide isomers may facilitate self-reactivity invoking the desired dimer- or trimerisation (Scheme 6.3.7).
Initial exposure of enamide 501 to Terada’s conditions yielded no products. After a suitable literature investigation it was decided to explore a number of both Lewis and Brønsted acids for promoting self-reactivity of 501 (Table 6.3.1, entries 1 - 4). Preliminary examination of BF₃.OEt₂ as a Lewis acid (Scheme 6.3.8) presented exciting results. Mass spectral analysis of the crude reaction mixture showed no starting material present and a mass peak corresponding to a dimeric product. TLC analysis confirmed the consumption of starting material 501, but a number of new product spots had appeared, including one major spot. Preparative TLC was used to separate each of the products and the major one was assigned as dimeric compound 515 after extensive NMR spectroscopy experimentation (Chapter 8). As expected, isomerisation between the imine and enamide tautomers had occurred under acidic conditions. Interestingly, however, the most nucleophilic position of 501 had proven to be position two of the indole ring as opposed to the desired reactivity at the benzylic position of the indole.
Each of the products isolated from the reaction were also analysed by mass spectral analysis and all were confirmed to be dimeric products. However, as the major isomer was only isolated in 37% yield it was decided that detailed NMR spectroscopy of each of the remaining products would be futile.

In the presence of both camphor sulfonic acid (CSA) and TFA, dimerisation was also facilitated albeit producing the same undesired coupled product 515. Sulfuric acid led to complete decomposition of starting material to yield unidentifiable potentially polymeric materials.
As the natural reactivity of this species 501 was not desirable, it was decided to try and tune the reactivity of the indole skeleton by introduction of a nitro group at the 6-position of the indole ring (Scheme 6.3.9). The idea that this may in fact mimic or enhance any effect that bromine may invoke in natural araioasamine biosynthesis was appealing.

Scheme 6.3.9.

It was thought that decreasing the reactivity of the indole ring could prevent reaction at the 2-position and allow preferential enamide dimerization. Synthesis of the 6-nitro analogue 516 of indole 501 is presented in Scheme 6.3.9. Unfortunately, incorporation of the nitro functionality prevented any dimerisation reactivity of the system as examined in Table 6.3.2, entries 1 - 4.

6.4 Indole trimerisation.

Unanticipated problems experienced in initial synthetic endeavours were obvious in hindsight. The highly conjugated nature of the enam ide indole systems generated, ‘confused’ positions in the molecular architecture. For instance, the imino carbon (Figure 6.4.1) of imine 501a would typically be electrophilic, however, tautomerisation to enam ide 501 would facilitate electron donation from the indole ring and imply nucleophilic characteristics on the same imino carbon.

To circumvent this unwanted reactivity it was thought to negate the effects of the indole by reducing the ring system to an indoline moiety. This tactic has previously been successfully used in the laboratory of E.J. Corey in the total synthesis of okaramine N 521 (Scheme...
The need to install a tert-prenyl functionality on the indole ring nitrogen required a reduction of the indole to facilitate known reactivity. Gribble reduction of tryptophan derivative 522 generated the desired indoline 523, which upon exposure to copper catalysed alkylative conditions with 2-acetoxy-2-methyl-3-butyne 524, yielded 525. Rearomatisation of the indoline core was obtained utilising DDQ. Selective reduction of the ethynyl group to the desired vinyl functionality under Pd catalysed hydrogenation gave the desired okaramine N precursor 526. Although a rather lengthy procedure to simply introduce a tert-prenyl moiety, it enabled the desired target to be synthesised and permitted the completion of okaramine N 521.

Since this publication the direct installation of tert-prenyl groups to indole nitrogens has been described by Baran and co-workers (Scheme 6.4.1).

**Scheme 6.4.1.**

In the context of our araiosamines synthesis, the thought arose that harnessing the indole reactivity by negating the conjugative effects could be beneficial. This was to be employed by utilising indoline as an indole surrogate, as mentioned. With a desire to incorporate Terada’s trimerisation conditions, we set about designing our indoline precursor. Previous work in the literature for the formation of aldehyde 527 (Scheme 6.4.2) was pivotal to our synthetic planning and in three steps enabled the synthesis of imine 528. Bromoaniline 529 was bis-allylated successfully using LDA and allyl bromide to generate protected aniline 530.
Next, the mechanistically interesting ring closing reaction was employed to quickly generate structural complexity. Allyl protected bromoaniline 530, upon exposure to t-BuLi, undergoes lithium transmetalation (531). Subsequent 5-exo cyclisation generated intermediate 532 which can be exposed to a variety of electrophiles to produce highly derivatised indolines (Scheme 6.4.3). In our case, addition of DMF introduced the required aldehyde moiety. As previously employed, Ti(Oi-Pr)₄ mediated condensation of Davis’ sulfinamide 506 with aldehyde 527 proved fruitful and generated imine 528 in good yield (Scheme 6.4.2; 62%).

In a revealing report from the laboratory of Ellman and co-workers, an intermolecular self-condensation of sulfinimines utilising basic conditions was presented. Under these conditions, enamide tautomerisation occurs and, assuming only half an equivalent of the appropriate base is used, the generated enamides should condense with the desired remaining imine. The presence of Ellman’s chiral auxiliaries inferred good diastereomeric control over this reaction (Scheme 6.4.4).
An analogous reaction was thought to be feasible for imine 528 to produce the desired dimeric indoline containing compound. Exposure of 528 to identical reaction conditions failed to generate any corresponding product, but instead, afforded the starting material (Scheme 6.4.5). Disappointed by this preliminary result our attention turned to the addition of different nucleophiles to imine 528.

A variety of different indole nucleophiles were prepared and their reactivity with imine 528 investigated. Further investigations in the Baran laboratories succeeded in coupling ester 533a with imine 528 under basic conditions. Subsequent re-oxidation of the indoline core using chloranil proved effective in forming an indole dimeric core 534 of the araiosamine natural products (Figure 6.4.2). This synthetic route was abandoned due to the laborious chemistry involved and the unacceptable reaction step count.
6.5. Claisen Condensation.

The interesting biosynthesis of pyrone derivative 535 incorporates a Claisen condensation to quickly from a trimeric compound which can then undergo cyclisation (Scheme 6.5.1). The similarities to our desired trimerisation and resulting cyclisation for the synthesis of araiosamines A-D generated an interest in utilising Claisen reactivity in our forward synthetic planning. An overall lowering of the oxidation state of the pyrone would provide an analogous oxygen containing heterocycle to our desired advanced intermediate 536.

Scheme 6.5.1.

A number of suitable Claisen and cross Claisen condensation precursors were synthesised including ester 533a, acid chloride 533b, thioester 534c, carboxylic acid 535d and anhydride 535e. Self Claisen condensation reactions were evaluated utilising ester 533a with a variety of different bases (Table 6.5.1, entries 1-4); however, no condensation product was detected. The use of Ti(Oi-Pr)_4 has proven in the literature to be an effective additive for promoting
numerous Claisen condensation reactions. In our case however no notable effect was detected.

In an attempt to utilise the cross Claisen condensation reaction, ester 533a was reacted with 533b, 533c, 533d and 533e, separately. Ester 533a was exposed to basic conditions at -78 °C and subsequently each of the coupling partners were added respectively (Table 6.5.1; entries 5-8). As previously experienced with these substrates no reactivity was observed. The use of this type of reactivity was obviously incompatible with our indole substrates.

Table 6.5.1. Investigations into Claisen and cross Claisen reactivity.\(^a\)

6.6. Alkyne trimerisation.

The Larock indole synthesis is a heteroannulation reaction between an iodoaniline and a disubstituted alkyne using catalytic amounts of palladium to generate highly functionalised indoles (Scheme 6.6.1).^{263}

Scheme 6.6.1.

\[
\begin{array}{c}
\text{Pd(OAc)}_2 \\
\text{LiCl, base, solvent}
\end{array} \quad \text{R}^S = \text{smaller substituent} \quad \text{R}^L = \text{larger substituent}
\]

The catalytic cycle is proposed to start with Pd(II)OAc\(_2\) being reduced to Pd(0) followed by coordination of a chloride anion to form a chloride ligated zerovalent palladium species. Subsequent oxidative addition of the aryl iodide to the Pd(0) species is followed by coordination of the alkyne moiety to the Pd atom. Syn insertion into the aryl-palladium bond, nitrogen displacement of the halide in the resulting vinylic palladium intermediate to form a six membered heteroatom containing palladacycle and reductive elimination form the desired indole. Pd(0) is also regenerated to continue the catalytic cycle (Scheme 6.6.2).
The synthetic utility of the Larock indole synthesis is surmised in its broad application throughout natural product chemistry. Due to the complicated reactivity of the indole system it is often beneficial to have indole precursors in place throughout a chemical synthesis and then perform a late stage indole forming reaction such as a Larock annulation. It is, therefore, possible to have either a disubstituted alkyne or an iodoaniline and transform them into the desired indole at the necessary stage in a synthesis. Selected examples of the ubiquitous nature of the Larock reaction in natural product chemistry are displayed in Scheme 6.6.3.
The possibility for forming typically challenging large rings (6 – 28 membered rings) was recognised by Boger and co-workers in 2013. Derivatised bromoanilines 538 containing an aliphatic linker moiety with a terminal protected alkyne were exposed to typical Larock conditions to generate the desired indole containing macrocycles 539 (Scheme 6.6.3, A). The Baran laboratory has a fond history of utilising the Larock indole synthesis en route to a number of architecturally complex natural products. The formation of a carbon nitrogen bond between the three position of an indole and the nitrogen atom of another indole molecule provided to be a daunting challenge. Initial attempts to introduce a leaving group at the three position of an indole, followed by nucleophilic displacement by a nucleophile proved ineffective. Eventually, the exposure of iodoaniline to NIS generated a haloamine, providing...
a suitably electrophilic nitrogen source. Exposure to a nucleophilic indole constructed the required carbon nitrogen bond (Scheme 6.6.3, B). Now the molecule 540 was perfectly primed for a Larock reaction and in the presence of alkyne 541, under suitable conditions, compound 542 was formed.\(^{265}\) Cook et al. have also effectively used the Larock reaction in their synthesis of tryptophan derivative 543 en route to the natural product fuchsiaefoline (Scheme 6.6.3, C).\(^{266}\)

The idea to form a trimeric alkyne analogue 544 of the araiosamines and introduce the indoles in a late stage with a triple Larock reaction seemed a potential method for coping with the problematic indole reactivity encountered to date (Scheme 6.6.4).

Scheme 6.6.4.

Retrosynthetic analysis of trimeric alkyne 544 provided enamide 545, which upon exposure to Terada’s cyclising conditions could generate our desired compound 544 (Figure 6.6.1). It was hoped that, by incorporating such a sterically bulky protecting group as the triisopropylsilyl group at the terminal alkyne position, unwanted side reactivity could be avoided. The conjugated nature of the molecule however was an initial concern.
Propargyl alcohol 546 was protected at the terminal alkyne position by exposure to TIPSCl to provide compound 547. Oxidation of the primary alcohol 547 to aldehyde 548 was enabled using IBX. A mild modification of the Horner-Wadsworth-Emmons (HWE) reaction generated olefin 549 in primarily trans configuration, as it is typical for this type of reactivity. Basic hydrolysis of ester 549 formed carboxylic acid 550 which then underwent acyl azide formation and subsequent Curtius rearrangement to prepare enamide 545 (Scheme 6.6.5.).

With an unproblematic route to enamide 545 in hand, our attention turned to the elusive trimerisation reaction. Initial efforts attempted to replicate Terada’s conditions with the use of chiral phosphoric acid 514. Disappointingly, after a screening of acidic conditions the only observable product was cis-trans isomerization of the olefin (Table 6.6.1, entries 1 - 4).
Table 6.6.1. Investigations into trimerisation reaction of enamide monomer 545.\(^a\)

\end{array}
\]

\(^a\) Additive (1 eq.), 12 h.

It was therefore concluded that trimerisation to afford advanced intermediates in the synthesis of the araiosamine natural products is unproductive and was terminated at this point. The substituted nature of the enamides used in these trimerisation studies has influenced the efficacy of this reaction and has proven unsuccessful for the formation of highly substituted piperidines (Figure 6.6.2).

![Proposed pre-transition state assembly of chiral phosphoric acid mediated addition of enamides to imines.](image)

Further studies are ongoing into the synthesis of araiosamines A-D in the Baran laboratories.
7. Conclusions and Future Work.

7.1. Conclusions.

This project has resulted in the development of three methodologies for the synthesis of biologically interesting guanidine containing compounds.

1) The first of these methods enables the rapid construction of 2-(arylamino)tetrahydro-1,4,5,6-pyrimidines 367. This methodology incorporated a Pd mediated cross coupling reaction between aryl bromides 357 and 2-aminopyrimidine 346 followed by a Pd catalysed hydrogenation to afford the desired guanidine products in good to excellent yields (Scheme 7.1.1, 64 - 98%). In this way 11 guanidine containing compounds were prepared containing a variety of appendages on the arylamino moiety including electron withdrawing and electron donating substituents.

\[
\text{Scheme 7.1.1}
\]

2) The next methodology developed introduced the use of 2-amino-4,6-dimethoxypyrimidine 384 as a guanidine precursor (Scheme 7.1.2). Thus, following the Buchwald-Hartwig approach (Scheme 7.1.2, A) the reaction of aryl bromides 357a-l with 2-amino-4,6-dimethoxypyrimidine 384 in the presence of Pd\(_2\)(dba)_3 as a Pd source, Xantphos 352 as a ligand and NaO-t-Bu as a base, it was possible to achieve a library of 13 arylamino-4,6-dimethoxypyrimidine derivatives 392a-l that by further treatment with HCl (6M) and acetic acid at 100 °C were cleaved to render the corresponding 13 guanidine hydrochloride salts 394a-l.
Alternatively, treatment of alkyl amines 401a-h with 2-amino-4,6-dimethoxypyrimidine 385 in isopropanol, using NEt₃ as a base at reflux (Scheme 7.1.2, B) yielded the corresponding 8 alkylamino-4,6-dimetoxy pyrimidines 402a-h that were cleaved to the corresponding 8 guanidinium salts 403a-h using HCl (4M) at 80 °C.

This approach has shown to be very useful and versatile for the preparation of both aryl and alkyl guanidine derivatives allowing even for the use of orthogonal protective groups such as Fmoc.

This method of introducing a guanidine functional group has a number of characteristics which make it favourable to other known methods of guanidylation namely:

1. Environmentally friendly.
2. Atom economical in comparison with typical guanidine protecting groups.
3. Cost effective.
4. Typically no column chromatography required.
To surmise these points a comparison of typical guanidylating reagents with 2-amino-4,6-dimethoxypyrimidine 384 employed for the synthesis of aryl guanidines is presented in Figure 7.1.1.

Figure 7.1.1. A comparison of typically employed guanidylating agents with 2-amino-4,6-dimethoxypyrimidine 384.

3) The last method developed for preparing biologically interesting guanidine containing compounds, employed a cascade cyclisation reaction to form a spiro guanidine aminal structure (Scheme 7.1.3, A). Thus, unmasking of an amino group of 456 by the removal of the phthalimide protecting group facilitated an intramolecular cascade reaction forming an unprecedented spiro guanidine aminal 462.

During this synthetic endeavour $N$-benzyl dihydroclathrodin 446 was synthesised (Scheme 7.1.3, B). The discovery that the guanidinium cation was more nucleophilic than the amide of compound 444 resulted in condensation of the guanidine onto the ketone forming the 2-aminoimidazole portion of dihydroclathrodin 446.

\]

Finally initial attempts to synthesis the araiosamine family of natural products (Figure 7.1.2) was conducted under the supervision of Prof. Baran at the Scripps Research Institute.

Figure 7.1.2. Araiosamine C.

The focus of our attention was to imitate the proposed biosynthesis of araiosamines A-D by means of an enamide trimerisation reaction (Figure 7.1.3).
7.2. Future Work.

After the success of our developed guanidylation reaction by means of cleavage of the 2-amino-4,6-dimethoxypyrimidine ring it is hoped that this procedure could be further investigated to find more facile methods for ring cleavage. A more gentle method of cleavage would enable this new guanidine precursor to find applications in peptide chemistry, an area which would greatly benefit from a new guanidine protecting group. Lewis acidic conditions may potentially facilitate the desired transformation (Scheme 7.2.1).

As well as finding uses in peptide chemistry this methodology would be found exceptionally useful in the synthesis of guanidine natural products. Due to the stability of the pyrimidine system this protecting group would allow for the early stage installation of the guanidine functionality which is extremely rare. The system would then be untouched by the typical conditions known to deprotect guanidines.

The methods developed will be applied to the synthesis of potential α2-adrenoceptor (α2-AR) antagonists and minor groove binders (MGBs). It is intended that spiro guanidine aminals will also be incorporated into new α2-ARs antagonists and MGBs.
The synthesis of aryl analogues of dibromophakellin 23 would enable the rapid construction of a vast library of guanidine containing compounds which could find uses as $\alpha_2$-AR antagonists (Figure 7.2.2).

This developed cyclisation reaction could also be applied to other cascade sequences such as the condensation of an amine onto a ketone followed by the formation of a carbon nucleophile by means of Grignard chemistry (Scheme 7.2.1). This would generate synthetically useful spirocyclic pyrrolidine derivatives.

Scheme 7.2.1.
The araiosamine family of natural products is currently being synthesised at the Scripps Research Institute in Prof. Baran’s laboratories by Ming Yan and co-workers. Routes developed include an aza-Achmatowicz reaction to form the piperidine core (Scheme 7.2.2, A) and also a Pd catalysed annulation reaction (Scheme 7.2.2, B).

8. Experimental procedures and data.

**General Procedures.**

Reagents were purchased at the highest commercial quality and used without further purification, unless otherwise stated. Dry diethyl ether (Et₂O), dichloromethane (CH₂Cl₂), acetonitrile (CH₃CN), toluene, tetrahydrofuran (THF), methanol (MeOH), and triethylamine (Et₃N) were obtained by distillation (as described by Vogel) and stored over 4 Å molecular sieves. Yields refer to chromatographically and spectroscopically (¹H NMR) homogeneous materials, unless otherwise stated. Reactions were monitored by thin layer chromatography (TLC) carried out on 0.25 mm E. Merck silica gel plates (60F-254) using either UV light as the visualizing agent or an acidic mixture of anisaldehyde, phosphomolybdic acid, or ceric ammonium molybdate, or basic aqueous potassium permanganate (KMnO₄), or ninhydrin and heat as developing agents. E. Merck silica gel (60, particle size 0.0430–0.063 mm) was used for flash column chromatography. Preparative thin layer chromatography (PTLC) separations were carried out on 0.25 or 0.50 mm E. Merck silica gel plates (60F-254). Concentration of organic solvents was performed on a rotary evaporator under reduced pressure followed by further evacuation using a two-stage mechanical pump. NMR spectra were recorded on Bruker DPX-600 and Bruker DPX-400 instruments operating at 400.13 MHz and 600.1 MHz for ¹H NMR; 100.6 MHz and 150.9 MHz for ¹³C-NMR and calibrated using residual undeuterated solvent as an internal reference (CHCl₃ @ 5.726 ppm ¹H NMR, δ 77.16 ¹³C NMR; CH₂Cl₂ @ 5.32 ppm ¹H NMR, δ 53.84 ppm ¹³C NMR). The following abbreviations (or combinations thereof) were used to explain ¹H NMR multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, quin. = quintet, m = multiplet, br = broad. High-resolution mass spectra (HRMS) were measured on a Micromass LCT electrospray TOF instrument with a WATERS 2690 autosampler and methanol/acetonitrile as carrier solvent. Melting points were determined using a Stuart Scientific Melting Point SMP1 apparatus and are uncorrected. Infrared spectra were recorded on a Perkin Elmer Spectrum One FT-IR Spectrometer equipped with a Universal ATR sampling accessory.
HPLC purity analysis was carried out using a Varian ProStar system equipped with a Varian Prostar 335 diode array detector and a manual injector (20 μL). For purity assessment, UV detection was performed at 245 nm and peak purity was confirmed using a purity channel. The stationary phase consisted of an ACE 5 C18-AR column (150 × 4.6 mm), and the mobile phase used the following gradient system, eluting at 1 mL/min: aqueous formate buffer (30 mM, pH 3.0) for 10 minutes, linear ramp to 85% methanol buffered with the same system over 25 minutes, hold at 85% buffered methanol for 10 minutes. Minimum requirement for purity was set at 95.0%.

Compounds are assigned arbitrary numbers for assignment of the NMR spectrum and these numbers do not correspond to the naming of the compound.
8.1. 2-(Arylamino)-tetrahydro-1,4,5,6-pyrimidines.

Optimisation of the Pd catalysed coupling of 2-chloropyrimidine with aniline.\(^a\)

\]

\(^a\) Aniline (1.5 mmol), base (1.5 mmol), 2-chloropyrimidine (1.0 mmol), Pd\(_2\)(dba)_3, ligand, solvent (1.5 mL/mmol 2-chloropyrimidine 345), 12 h. \(^b\) 24 h. \(^c\) 48 h.
Method A: The coupling of anilines with 2-chloropyrimidine.

To an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg) and Xantphos (3 mol%, 17 mg) was added 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.), base (1.5 mmol, 1.5 eq.) and aniline (1.5 mmol, 1.5 eq.). The Schlenk tube was then put under vacuum and back filled with argon three times. To this was added freshly distilled toluene (1.5 mL). The Schlenk tube was then placed in an oil bath with vigorous stirring at 95 °C. The reaction was monitored by TLC and once deemed complete (typically 8 – 12 h, TLC analysis) was cooled to rt and diluted with EtOAc (10 mL). The reaction was then filtered through a pad of Celite© with any remaining residues in the Schlenk tube being further washed with another portion of EtOAc (5 mL). To the filtered solution was added H$_2$O (10 mL) and the layers separated. The aqueous phase was further extracted with EtOAc (3 × 10 mL) and the combined organic layers washed with brine (20 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the crude product. This residue was then purified by column chromatography (silica gel, hexanes:EtOAc, 100:0 → 60:40) to yield the target compound.

2-Anilinopyrimidine (353)

Following Method A aniline (91 μL, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaOt-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 95 °C for 12 h and then worked up according to Method A.

Yield: 88% (150 mg).

Physical State: Colourless crystal.

Mp: 112-115 °C. (Lit. 115 - 116 °C)$^{286}$

Rf: 0.40 (hexanes:EtOAc, 80:20).

IR $\nu_{\text{max}}$(film)/cm$^{-1}$: 3254 (NH), 3054, 1609, 1576, 1444, 793, 746, 698.
\textbf{Chapter 8 Experimental procedures and data}

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 6.75 (t, $J = 5.0$ Hz, 1H, H-5), 7.09 (t, $J = 7.2$ Hz, 1H, H-4$'$), 7.38 (app. t, 2H, H-3$'$), 7.43 (br s, NH) 7.64 (d, $J = 7.2$ Hz, 2H, H-2$'$), 8.45 (d, $J = 5.0$ Hz, 2H, H-4, 6$'$).

$^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ 112.1 (CH), 119.1 (2CH), 122.2 (CH), 128.5 (2CH), 138.9 (qC), 157.6 (2CH), 159.7 (qC).

HRMS ($m/z$ ESI$^+$): Found 172.0867 (M$^+$ + H. C$_{10}$H$_{10}$N$_3$ Requires 172.0869).

2-(4-Methoxyanilino)pyrimidine (355b)

Following Method A $p$-anisidine (184 mg, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaO/-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 100 $^\circ$C for 10 h and then worked up according to Method A.

Yield: 87\% (175 mg).

Physical State: White solid.

Mp: 129-131 $^\circ$C. (Lit. 125 - 126 $^\circ$C$^{287}$)

R$_f$: 0.36 (hexanes:EtOAc, 80:20).

IR $\nu_{\text{max}}$(film)/cm$^{-1}$: 3260 (NH), 2980, 1712, 1620, 1584, 1208, 1155, 852, 819, 777.

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 3.82 (s, 3H, OCH$_3$), 6.68 (t, $J = 5.0$ Hz, 1H, H-5), 6.91 (d, $J = 9.0$ Hz, 2H, H-3$'$,5$'$), 7.34 (br s, NH), 7.49 (d, $J = 9.0$ Hz, 2H, H-2$'$,6$'$), 8.39 (d, $J = 5.0$ Hz, 2H, H-4,6$'$).

$^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ 55.0 (CH$_3$), 111.6 (CH), 113.8 (2CH), 119.8 (qC), 121.9 (2CH), 131.8 (qC), 157.6 (2CH), 160.2 (qC).

HRMS ($m/z$ ESI$^+$): Found 202.0982 (M$^+$ + H. C$_{11}$H$_{12}$N$_3$O Requires 202.0980).
2-(2-Methoxyanilino)pyrimidine (355c)

Following Method A o-anisidine (184 mg, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaOt-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 100 °C for 10 h and then worked up according to Method A.

Yield: 72% (144 mg).

Physical State: Colourless crystal.

Mp: 121-124 °C.

R$_f$: 0.39 (hexanes:EtOAc, 80:20).

IR $v_{\text{max}}$ (film)/cm$^{-1}$: 3255 (NH), 2972, 1608, 1576, 1444, 1251, 973, 793, 779, 693, 669.

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 3.91 (s, 3H, OCH$_3$), 6.71 ($t, J = 5.0$ Hz, 1H, H-5), 6.92 (d, $J = 7.0$ Hz, 1H, H-3'), 7.02 (m, 2H, H-4',5'), 7.83 (br s, NH), 8.45 (d, $J = 5.0$ Hz, 1H, H-6'), 8.53 (d, $J = 7.0$ Hz, 2H, H-4,6).

$^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ 55.2 (CH$_3$), 109.5 (CH), 111.9 (CH), 118.1 (CH), 120.4 (CH), 121.4 (CH), 128.7 (qC), 147.5 (qC), 157.5 (2CH), 159.5 (qC).

HRMS ($m/z$ ESI$^+$): Found 202.0988 (M$^+$ + H. C$_{11}$H$_{12}$N$_3$O Requires 202.0980).
2-[4-(N,N-Dimethylamino)anilino]pyrimidine (355d)

Following Method A N,N-dimethyl-p-phenylenediamine (204 mg, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaO-t-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 100 °C for 12 h and then worked up according to Method A.

Yield: 72% (154 mg).

Physical State: Dark red/black solid.

Mp: 137-140 °C.

R$_f$: 0.50 (hexanes:EtOAc, 80:20).

IR $\nu_{\text{max}}$ (film)/cm$^{-1}$: 3237 (NH), 3155, 2849, 1600, 1582, 1564, 1364, 991, 793, 704.

$^1$H NMR (400 MHz, CDCl$_3$): δ 2.92 (s, 6H), 6.60 (t, $J$ = 4.8 Hz, 1H, H-5), 6.76 (d, $J$ = 8.8 Hz, 2H, H-3',5'), 7.17 (br s, NH), 7.38 (d, $J$ = 8.8 Hz, 2H, H-2',6'), 8.34 (d, $J$ = 4.8 Hz, 2H, H-4,6).

$^{13}$C NMR (100 MHz, CDCl$_3$): δ 40.9 (2CH$_3$), 111.6 (CH), 113.3 (2CH), 122.5 (2CH), 128.9 (qC), 147.6 (qC), 158.3 (2CH), 161.0 (qC).

HRMS (m/z ESI$^+$): Found 215.1298. (M$^+$ + H). C$_{12}$H$_{15}$N$_4$ Requires 215.1297).
2-(4-Fluoroanilino)pyrimidine (355e)

Following Method A 4-fluoroaniline (166 mg, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaO-t-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 100 °C for 12 h and then worked up according to Method A.

Yield: 50% (94 mg).

Physical State: Pale yellow crystal.

Mp: 147-150 °C. (Lit. 148 - 149 °C)$^{287}$

Rf: 0.36 (hexanes:EtOAc, 80:20).

IR $\nu_{\text{max}}$ (film)/cm$^{-1}$: 3259 (NH), 2972, 1713, 1619, 1584, 1506, 1416, 1280, 791, 709.

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 6.74 (t, $J = 5.0$ Hz, 1H, H-5), 7.06 - 7.07 (m, 2H, H-3',5'), 7.51 (br s, NH), 7.57 - 7.58 (m, 2H, H-2',6'), 8.43 (d, $J = 5.0$ Hz, 2H, H-4,6).

$^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ 112.1 (CH), 114.9 (2CH, $J_{CF} = 23.0$ Hz), 121.1 (2CH, $J_{CF} = 15.0$ Hz), 134.8 (qC), 157.0 (qC), 157.6 (2CH), 159.4 (qC, $J_{CF} = 240.0$ Hz).

HRMS ($m/z$ ESI$^+$): Found 190.0789 (M$^+$ + H. C$_{10}$H$_9$FN$_3$ Requires 190.0780).
2-(2-Fluoroanilino)pyrimidine (355f)

Following Method A 2-fluoroaniline (166 mg, 1.5 mmol, 1.5 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-chloropyrimidine (114 mg, 1.0 mmol, 1.0 eq.) and NaOt-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 100 °C for 12 h and then worked up according to Method A.

Yield: 49% (93 mg).

Physical State: Yellow solid.

Mp: 110-114 °C. (Lit. 117 - 118 °C$^{268}$)

Rf: 0.38 (hexanes:EtOAc, 80:20).

IR $\nu_{max}$ (film)/cm$^{-1}$: 3249 (NH), 3014, 1576, 1489, 1439, 1252, 1106, 1030, 795, 753.

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 6.73 (t, $J = 5.0$ Hz, 1H, H-5), 6.97 (m, 1H, H-3'), 7.09 (m, 2H, H-4',5'), 7.98 (br s, NH), 8.38 (d, $J = 7.6$ Hz, 1H, H-6'), 8.43 (d, $J = 5.0$ Hz, 2H, H-4,6).

$^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ 112.5 (CH), 114.3 (CH, $J_{CF} = 20.0$ Hz), 114.5 (CH), 122.2 (CH, $J_{CF} = 8.0$ Hz), 123.7 (CH, $J_{CF} = 8.0$ Hz), 127.5 (qC, $J_{CF} = 20.0$ Hz), 151.3 (qC, $J_{CF} = 260.0$ Hz), 157.5 (2CH), 159.5 (qC).

HRMS (m/z ESI$^+$): Found 190.0785 (M$^+$ + H, C$_{10}$H$_9$FN$_3$ Requires 190.0780).

\textsuperscript{a} 2-aminopyrimidine (1.5 mmol), base (1.5 mmol), aryl bromide (1.0 mmol), Pd$_2$(dba)$_3$, ligand, solvent (1.5 mL), 12 h. \textsuperscript{b} 24 h. \textsuperscript{c} 48 h.
Method B - The coupling of 2-aminopyrimidine with aryl bromides.

To an oven dried Schlenk tube charged with Pd\(_2\)(dba)\(_3\) (2 mol%, 18 mg) and Xantphos 352 (3 mol%, 17 mg) was added 2-aminopyrimidine (142 mg, 1.5 mmol, 1.5 eq.), base (1.5 mmol, 1.5 eq.) and aryl bromide (1.0 mmol, 1.0 eq.). The Schlenk tube was then put under vacuum and back filled with argon three times. To this was added freshly distilled toluene (1.5 mL). The Schlenk tube was then placed in an oil bath with vigorous stirring at 95 °C. The reaction was monitored by TLC and once deemed complete (typically 8 – 12 h) was cooled to rt and diluted with EtOAc (10 mL). The reaction was then filtered through a pad of Celite\textsuperscript{©} with any remaining residues in the Schlenk tube being further washed with another portion of EtOAc (5 mL). To the filtered solution was added H\(_2\)O (10 mL) and the layers separated. The aqueous phase was further extracted with EtOAc (3 × 10 mL) and the combined organic layers washed with brine (20 mL), dried over MgSO\(_4\) and concentrated under reduced pressure to afford the crude product. This residue was then purified by column chromatography (silica gel, hexanes:EtOAc, 100:0 → 60:40) to yield the target compound.

2-Anilinopyrimidine (353)

![Chemical structure]

Following Method B bromobenzene (1575 μL, 15.0 mmol, 1.0 eq.) was added to an oven dried Schlenk tube charged with Pd\(_2\)(dba)\(_3\) (2 mol%, 270 mg), Xantphos (3 mol%, 255 mg), 2-aminopyrimidine (2130 mg, 30.0 mmol, 1.5 eq.) and NaOr-Bu (2160 mg, 30.0 mmol, 1.5 eq.). After air extraction and backfilling with Ar, toluene (22.5 mL) was added. The reaction was stirred at 95 °C for 12 h and then worked up according to Method B.

Spectral data for this compound were consistent with those of compound 353 prepared according to Method A.

Yield: 98% (2513 mg).

Physical State: Colourless crystal.
Chapter 8 Experimental procedures and data

Mp: 112-113 °C.

Rf: 0.40 (hexanes:EtOAc, 80:20).

IR νmax (film)/cm⁻¹: 3234 (NH), 3067, 2960, 1865, 1606, 1583, 1446, 1300, 1257, 1232, 1034, 1008, 885, 822, 787, 676, 660.

**Method C - Hydrogenation of $N$-aryl-2-aminopyrimidines**

To $N$-aryl-2-aminopyrimidine (1.0 mmol) in MeOH (4.0 mL) was added 10% Pd/C (120 mg). To this was added aqueous HCl (1M, 1.0 mL). The mixture was then hydrogenated at atmospheric pressure for 10-12 hrs with vigorous stirring. It was then filtered through a pad of Celite© and concentrated. The residue was then purified by diluting the compound in the minimum amount of H$_2$O and passing through a reverse phase silica plug, using H$_2$O/MeCN (95:5) as the eluent. The solution was then concentrated under reduced pressure to yield the title compounds as the tetrahydropyrimidine hydrochloride salts.
2-Anilino-1,4,5,6-tetrahydropyrimidine hydrochloride (365)

Following Method C to 2-anilinopyrimidine 353 (85 mg, 0.50 mmol) in MeOH (2.0 mL) was added 10% Pd/C (60 mg). To this was added aqueous HCl (1M, 0.50 mL). The reaction was stirred at rt under 1 atm of hydrogen for 12 h and then worked up according to Method C.

Yield: 97% (102 mg).

Physical State: Colourless gel.

Mp: -

Rf: Baseline (EtOAc).

8.2. 2-Aminopyrimidines as a guanidine precursor.

**Method D - General procedure for the coupling of aryl halides with 2-amino-4,6-dimethoxypyrimidine**

To an oven dried Schlenk tube charged with a stir bar, Pd$_2$(dba)$_3$ (2 mol%, 18 mg) and Xantphos 352 (3 mol%, 17 mg) was added 2-amino-4,6-dimethoxypyrimidine (1.5 mmol, 1.5 equiv, 232 mg), base (1.5 mmol, 1.5 equiv) and aryl halide (1.0 mmol, 1.0 equiv), if the aryl halide is a solid. The Schlenk tube was put under vacuum and back filled with argon three times. To this was added freshly distilled toluene (1.5 mL / mmol aryl halide). If the aryl halide was a liquid it was now added to the solution. The Schlenk tube was then placed in an oil bath with vigorous stirring at 95 °C. The reaction was monitored by TLC and once deemed complete (typically 6-12 h), was cooled to rt and diluted with EtOAc (10 mL). The reaction mixture was filtered through Celite© with any remaining residues in the Schlenk tube being washed out with a further amount of EtOAc (10 mL). The organic phase was then washed with water (20 mL). The aqueous phase was extracted with EtOAc (3 x 20 mL) and the combined organic layers washed with brine (30 mL), dried over MgSO$_4$ and concentrated under reduced pressure. The crude product was then purified by flash column chromatography (silica gel, hexanes:EtOAc, 100:0 → 60:40) to yield the target compound.

**2-Anilino-4,6-dimethoxypyrimidine (391)**

Following Method D bromobenzene (105 μL, 1.0 mmol, 1.0 eq.) was added to an oven dried Schlenk tube charged with Pd$_2$(dba)$_3$ (2 mol%, 18 mg), Xantphos (3 mol%, 17 mg), 2-amino-4,6-dimethoxypyrimidine (232 mg, 1.5 mmol, 1.5 eq.) and NaOt-Bu (144 mg, 1.5 mmol, 1.5 eq.). The reaction was stirred at 95 °C for 8 h and then worked up according to Method D.

Spectral data for this compound were consistent with those in the literature.$^{271}$

**Yield:** 96 % (221 mg).
Experimental procedures and data

231
General procedure for the cleavage of \( N \)-aryl-2-amino-4,6-dimethoxypyrimidine – Method E.

To an RBF (5 mL) containing \( N \)-aryl-2-amino-4,6-dimethoxypyrimidine (0.25 mmol, 1.0 equiv) in AcOH (0.210 mL) was added water (0.210 mL) and 12 M HCl (0.420 mL). To this was attached a reflux condenser making sure the joint was well greased. The RBF was then covered with aluminium foil and fully submerged in an oil bath at 100 °C (essential). The reaction was monitored by TLC, ensuring to basify all TLC samples using Et₃N, and once deemed complete was allowed cool to room temperature. The solution was washed with EtOAc (3 x 10 mL) and CH₂Cl₂/MeOH 80:20, 1 x 10 mL) to remove any unreacted starting materials and then the aqueous phase concentrated under reduced pressure to yield the target aryl guanidine as the hydrochloride salt.

Phenylguanidine hydrochloride (393)

Following Method E to 2-anilino-4,6-dimethoxypyrimidine 391 (58 mg, 0.25 mmol, 1.0 equiv) in AcOH (0.210 mL) was added water (0.210 mL) and 12 M HCl (0.420 mL). The reaction was stirred at 95 °C for 12 h and then worked up according to Method E.

Spectral data for this compound were consistent with those in the literature.\(^\text{145}\)

**N-Alkyl-2-amino-4,6-dimethoxypyrimidine Cleavage**

**Method F - General procedure for formation of N-substituted 2-amino-4,6-dimethoxypyrimidines.**

To amine (3.0 mmol, 3.0 eq.) in i-PrOH (2.0 mL) was added NEt₃ (416 μL, 3.0 mmol, 3.0 eq.). To this was added 2-chloro-4,6-dimethoxypyrimidine (174 mg, 1.0 mmol, 1.0 eq.). A greased reflux condenser was attached and the mixture heated to reflux (120 °C). The reaction was left at this temperature until deemed complete by TLC analysis, typically 6 – 12 h. The reaction was then allowed cool to room temperature and then diluted with either EtOAc (10 mL, substrates 402b and 402c) or Et₂O (10 mL, all other substrates). This was then washed with water (5 mL). The aqueous phase was then extracted with the appropriate solvent as previously used (EtOAc or Et₂O, 3 × 10 mL). The combined organic layers were then washed with brine (10 mL), dried over MgSO₄ and then concentrated under reduced pressure to afford the title compound in its crude form. Purification by column chromatography (silica gel, hexanes:EtOAc, 100:0 → 60:40) afforded the title compound.

**N-Benzyl-2-amino-4,6-dimethoxypyrimidine (386)**

Following Method F to benzylamine (327 μL, 3.0 mmol, 3.0 eq.) in i-PrOH (2.0 mL) was added NEt₃ (416 μL, 3.0 mmol, 3.0 eq.). To this was added 2-chloro-4,6-dimethoxypyrimidine (174 mg, 1.0 mmol, 1.0 eq.). The reaction was stirred at reflux (120 °C) for 12 h and then worked up according to Method F.

**Yield:** 90% (220 mg).

**Physical State:** White solid.

**Mp:** 64-65 °C.

**Rf:** 0.40 (hexanes:EtOAc, 90:10).
IR $\nu_{\text{max}}$ (film)/cm$^{-1}$: 3244 (NH), 3069, 3004, 2977, 2942, 1609, 1582, 1544, 1485, 1406, 1362, 1297, 1266, 1207, 1162, 1075, 1013, 952, 895, 848, 795, 732.

Chapter 8

Experimental procedures and data

N-(1-Aminoethen-2-yl)-2-amino-4,6-dimethoxypyrimidine (402c)

Following Method F to ethylenediamine (2000 µL, 30.0 mmol, 3.0 eq.) in i-PrOH (20.0 mL) was added NEt₃ (4160 µL, 30.0 mmol, 3.0 eq.). To this was added 2-chloro-4,6-dimethoxypyrimidine (1740 mg, 10.0 mmol, 1.0 eq.) in portions of 350 mg every hour over 5 h with only 340 mg being added on the 5th hour. The reaction was stirred at reflux (120 °C) for a further 12 h and then worked up according to Method F.

Yield: 86% (1700 mg -10 mmol scale).

Physical State: Orange oil.

Rr: 0.08 (EtOAc).

IR νmax (film)/cm⁻¹: 3293 (NH), 2947 (NH), 1575, 1542, 1456, 1420, 1363, 1348, 1210, 1192, 1156, 1010, 924, 793.

¹H NMR (400 MHz, D₂O): δ 2.92 (t, J = 6.0 Hz, 2H, H-1'), 3.48 (app. q, 2H, H-2'), 3.84 (s, 6H, OMe), 5.40 (s, 1H, H-5).

¹³C NMR (100 MHz, D₂O): δ 40.7 (CH₂), 42.6 (CH₂), 53.5 (2CH₃), 78.2 (CH), 161.7 (qC), 172 (2qC).

HRMS (m/z ESI⁺): Found 199.1192 (M⁺ + H. C₈H₁₅N₄O₂ Requires 199.1195).
4,6-Dimethoxy-2-(4-phenylpiperidine-1-yl)pyrimidine (402d)

Following Method F to 4-phenylpiperidine (483 mg, 3.0 mmol, 3.0 eq.) in i-PrOH (2.0 mL) was added NEt₃ (416 μL, 3.0 mmol, 3.0 eq.). To this was added 2-chloro-4,6-dimethoxypyrimidine (174 mg, 1.0 mmol, 1.0 eq.). The reaction was stirred at reflux (120°C) for 12 h and then worked up according to Method F.

Yield: 88% (264 mg).

Physical State: White powder.

Mp: 103-106°C.

Rf: 0.52 (hexanes:EtOAc, 90:10).

IR νₘₐₓ (film)/cm⁻¹:
- 3027, 2932, 2846, 1570, 1494, 1450, 1400, 1357, 1330, 1280, 1259, 1198, 1184, 1157, 1088, 1063, 1031, 987, 807, 788, 755.

**Method G - General procedure for pyrimidine ring cleavage**

To <i>N</i>-substituted 2-amino-4,6-dimethoxypyrimidine (0.25 mmol) was added 4M aqueous HCl (5.0 mmol, 20.0 eq., 1.250 mL) at 80 °C in a sealed tube. The reaction was left to stir until deemed complete by TLC analysis (8 – 16 h). The reaction was cooled to room temperature and then diluted with EtOAc (4 mL). The phases were then separated and the aqueous phase was further washed with EtOAc (2 × 5 mL). The aqueous phase was then washed with CH<sub>2</sub>Cl<sub>2</sub>/MeOH (85:15, 5 mL). The aqueous phase containing the guanidine compound was then concentrated under reduced pressure. If further purification was required then the guanidine product was diluted in the minimum amount of water and passed through a plug of reverse phase silica (C<sub>8</sub>) eluting with water to yield the title compound.

Piperidine-1-carboxamidine hydrochloride (403g)

Following Method G to 4,6-Dimethoxy-2-(piperidin-1-yl)pyrimidine 402g (56 mg, 0.25 mmol, 1.0 eq.) was added 4M aqueous HCl (5.0 mmol, 20.0 eq., 1.250 mL) at 80 °C in a sealed tube. The reaction was stirred at 80 °C for 12 h and then worked up according to Method G.

Spectral data for this compound were consistent with those in the literature.$^ {272}$

Yield: 88% (35 mg).

Physical State: Yellowish solid.

Mp: 185-188 °C (Lit. 186-187 °C).

Rf: Baseline (EtOAc).

$^1$H NMR (400 MHz, D$_2$O): δ 1.72 – 1.75 (m, 6H, H-3,4,5), 3.59 – 3.75 (m, 4H, H-2,6).

2-[Benzyl(2-ethylamino)carbamate]-4,6-dimethoxypyrimidine (404a)

To N-(1-aminoethyl-2-yl)-2-amino-4,6-dimethoxypyrimidine 402c (199 mg, 1.0 mmol, 1.0 eq.) in CH$_2$Cl$_2$ (4.0 mL) was added NEt$_3$ (138 μL, 1.0 mmol, 1.0 eq.). To this was added benzyl chloroformate (156 μL, 1.1 mmol, 1.1 eq.) at 0 °C. This solution was allowed warm to rt over 1 h and stirred for 4 h or until deemed complete (TLC analysis). The reaction was then diluted with water (5 mL) and EtOAc (10 mL). The layers were separated and the aqueous phase extracted with EtOAc (3 × 10 mL). The combined organic layers were then
Chapter 8  Experimental procedures and data

washed with brine (15 mL), dried over MgSO₄ and concentrated under reduced pressure. The crude residue was then purified by column chromatography (silica gel, hexanes:EtOAc, 90:10 → 60:40) to yield the target compound.

Yield: 90% (222 mg).

Physical State: White solid.

Mp: 60–61 °C.

Rf: 0.41 (hexanes:EtOAc, 60:40).

*N*-Benzyl pyrrole (434)

To freshly distilled pyrrole (6937 µL, 100.0 mmol, 1.0 eq.) in CH₂Cl₂ (160.0 mL) was added benzyl bromide (13060 µL, 110.0 mmol, 1.1 eq.) and *tetra*-butyl ammonium bromide (37210 mg, 100.0 mmol, 1.0 eq.) at 0 °C. To this was added NaOH (50.0 g in H₂O – 100.0 mL) slowly, ensuring the reaction mixture was kept at 0 °C. Once the addition was complete a reflux condenser was attached and the solution heated to 65 °C for 24 h. After this time the reaction was cooled to room temperature and diluted with CH₂Cl₂ (100 mL) and H₂O (100 mL). The solution was vigorously stirred for 5 min and then allowed to settle. The organic layer was separated and the aqueous phase extracted with CH₂Cl₂ (3 × 100 mL). The combined organic layers were then washed with 3M HCl (100 mL) followed by brine (100 mL). The organic layer was then dried over MgSO₄, concentrated under reduced pressure and then purified by vacuum distillation to afford the title compound.

Spectral data for this compound were consistent with those in the literature.²⁷⁴

**Yield:** 77% (12089 mg).

**Physical State:** Colourless oil.

**Mp:**

**Rf:** 0.33 (hexanes:EtOAc, 90:10).

**¹H NMR (400 MHz, CDCl₃):**

δ 5.10 (s, 2H, H-4), 6.20 (t, J = 2.0 Hz, 2H, H-3), 6.70 (d, J = 2.0 Hz, 2H, H-2), 7.20 (d, J = 8.0 Hz, 2H, H-5), 7.40 (m, 3H, H-6,7).
To trichloroacetyl chloride (8086 μL, 71.97 mmol, 1.0 eq.) in Et₂O (20.0 mL) at 0 °C was added \textit{N}-benzyl pyrrole 434 (11300 mg, 71.97 mmol, 1.0 eq.) in Et₂O (60.0 mL). This reaction was then stirred for 12 h at rt. After this time the reaction was then very cautiously quenched with a solution of sat. aq. NaHCO₃ (80 mL). The aqueous phase was then extracted with Et₂O (3 × 50 mL). The combined organic layers were then washed with brine (50 mL), dried over MgSO₄ and then concentrated under reduced pressure. The crude product was then purified by column chromatography (silica gel, hexanes:EtOAc, 70:30) to afford the target compound as a colourless oil which solidified upon standing to give an off white solid.

Spectral data for this compound were consistent with those in the literature.\textsuperscript{275}

\textbf{Yield:} 80\% (17272 mg).

\textbf{Physical State:} Colourless oil – off white solid.

^a BRSM.

**Method H – IBX oxidation.**

To pyrrole 437 (272 mg, 1.0 mmol, 1.0 eq.) in MeCN (10.0 mL) was added freshly prepared IBX (840 mg, 3.0 mmol, 3.0 eq.). The mixture was heated to 50 °C for 1.5 h or until complete consumption of starting alcohol as indicated by TLC. The reaction was cooled to rt and then diluted with MeCN (20 mL). The solution was then passed through a plug of Celite© and concentrated under reduced pressure to afford crude aldehyde 438 as a pale yellow oil.

**Method I – DMP oxidation.**

To pyrrole 437 (272 mg, 1.0 mmol, 1.0 eq.) in CH₂Cl₂ (10.0 mL) was added freshly prepared DMP (1272 mg, 3.0 mmol, 3.0 eq.). The reaction was stirred for 1 h or until complete consumption of starting alcohol as indicated by TLC. The reaction was then quenched by the addition of a solution of sat. aq. NaHCO₃ (5 mL), a solution of sat. aq. Na₂S₂O₃ (5 mL) and then diluted with CH₂Cl₂ (10 mL). The layers were separated and the aqueous phase was
washed with CH$_2$Cl$_2$ (3 × 10 mL). The combined organic layers were then washed with a solution of sat. aq. NaHCO$_3$ (10 mL) mixed with sat. Na$_2$S$_2$O$_3$ (10 mL). The combined organic layers were then washed with brine, dried with MgSO$_4$ and concentrated under reduced pressure to afford crude aldehyde 438 as a pale yellow oil.

**Method J** – Swern oxidation.

To oxalyl chloride (157 µL, 1.83 mmol, 1.83 eq.) in CH$_2$Cl$_2$ (5.0 mL) at -78 °C was added DMSO (332 µL, 4.67 mmol, 4.67 eq.) in CH$_2$Cl$_2$ (1.50 mL) over 10 min. This solution was stirred for a further 5 min and then alcohol 437 (272 mg, 1.0 mmol, 1.0 eq.) in CH$_2$Cl$_2$ (1.50 mL) and DMSO (0.5 mL) was added dropwise over 10 min maintaining the temperature at -78 °C. This mixture was then stirred for 1 h followed by the addition of NEt$_3$ (835 µL, 5 mL/6 mmol alcohol). The reaction was then allowed warm to rt over 1 h. After warming to rt the reaction was quenched by the addition of brine (10 mL). The layers were separated and the aqueous phase washed with CH$_2$Cl$_2$ (3 × 10 mL). The combined organic layers were then washed with brine (20 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the crude aldehyde 438 as a yellow oil.
1-Benzyl-N-(4-hydroxy-5-nitropentyl)-1H-pyrrole-2-carboxamide (441)

To crude aldehyde 438 (1470 mg, 5.0 mmol, 1.0 eq.) in THF (5.0 mL) was added t-BuOH (5.0 mL) and MeNO₂ (2.5 mL) at rt. To this was added KOt-Bu (140 mg, 1.25 mmol, 0.25 eq.) in one portion. The reaction was stirred for 10 h and subsequently quenched by the addition of water (20 mL) and EtOAc (50 mL). The layers were separated and the organic layer washed with a solution of sat. aq. NaHCO₃ (20 mL), H₂O (20 mL) and brine (20 mL). The combined aqueous phase was then extracted with EtOAc (3 × 20 mL). The combined organic layers were then dried over MgSO₄, and concentrated under reduced pressure to afford the crude product as an orange gel. This was then purified by column chromatography (silica gel, hexanes:EtOAc, 90:10 → 40:60) to afford the pure product.

Yield: 86% (1428 mg).

Physical State: Pale orange gel.

*Isolated yield

**Method K – SnCl₂ reduction.**

To nitro 441 (241 mg, 0.73 mmol, 1.0 eq.) in EtOAc (7.30 mL, degassed) was added SnCl₂·2H₂O (1304 mg, 5.79 mmol, 8.0 eq.) at rt. The reaction mixture was heated to 80 °C with a reflux condenser attached. The reaction was stirred for 4.5 h after which time it was cooled to rt and diluted with EtOAc (10 mL). The solution was then filtered through a pad of Celite® and concentrated under reduced pressure. The resultant mixture was then dissolved in CH₂Cl₂ (~2 mL) and then HCl (4 M in Et₂O) was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et₂O (5 mL) to afford the desired product as an off white solid (39%, 95 mg).

**Method L – Zinc reduction**

To nitro 441 (650 mg, 1.96 mmol, 1.0 eq.) in EtOH (6.8 mL) was added H₂O (1.6 mL) at rt. To this mixture was added Zn powder (642 mg, 9.82 mmol, 5 eq.) in one portion. Conc. HCl (1.2 mL, 12 M) was added dropwise to this vigorously stirred solution. The reaction was left to stir at rt for 5 h after which time the reaction was deemed complete by the full consumption of starting nitro 441 as indicated by TLC analysis. The reaction mixture was diluted with EtOAc and filtered through a double thickness of filter paper to remove the Zn residues. The mixture was concentrated under reduced pressure to afford the crude product. The resultant crude product was then dissolved in CH₂Cl₂ (~2 mL) and then HCl (4 M in
Et₂O was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et₂O (5 mL) to afford the desired product as an off white solid (30%, 198 mg).

**Method M – H₂, Pd/C reduction**

To nitro 441 (331 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd/C (10 wt-%, 150 mg). The flask was then hydrogenated (3 atm.) over a period of 7 h. The flask was flushed with argon, the solution diluted with EtOH (5 mL) and then filtered through a double thickness of filter paper. The product was concentrated under reduced pressure. The solution was then filtered through a pad of Celite® and concentrated under reduced pressure. The resultant mixture was then dissolved in CH₂Cl₂ (~2 mL) and then HCl (4 M in Et₂O) was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et₂O (5 mL) to afford the desired product (74%, 250 mg).

**1-Benzyl-N-(4-hydroxy-5-aminopentyl)-1H-pyrrole-2-carboxamide (442)**

Following Method M to nitro 441 (331 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd/C (10 wt-%, 150 mg). The flask was then hydrogenated (3 atm.) over a period of 7 h. The compound was then worked up and purified according to Method M.

**Yield:** 74% (250 mg).
Physical State: Off white viscous gel.

HSQC:
Method N for guanidylation.

To amine 442 (301 mg, 1.0 mmol, 1.0 eq.) in solvent (5.0 mL) was added NEt₃ (152 μL, 1.1 mmol, 1.1 eq.) followed by thiourea guanidylating agent (1.2 mmol, 1.2 eq.). The mixture was then cooled to 0 °C and the Lewis acid promoter (1.1 mmol, 1.1 eq.) was added in one portion. The reaction was then stirred for 10 h at the said temperature or until the starting amine 442 was fully consumed as indicated by TLC analysis. At this point the reaction was diluted with EtOAc (20 mL) and then filtered through a plug of Celite®. The organic layer was then washed with water (20 mL). The layers were separated and the aqueous phase extracted with EtOAc (3 × 30 mL). The combined organic phases were then washed with brine (20 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the crude product which was purified by column chromatography (silica gel, hexanes:EtOAc, 90:10 → 40:60) to afford the desired product.

<sup>a</sup> Gram scale procedures.
Method H – IBX oxidation.

To alcohol 450 (100 mg, 0.456 mmol, 1.0 eq.) in MeCN (4.0 mL) was added freshly prepared IBX (383 mg, 1.36 mmol, 3.0 eq.). The mixture was heated to 50 °C for 1.5 h or until complete consumption of starting alcohol as indicated by TLC. The reaction was cooled to rt and then diluted with MeCN (5 mL). The solution was then passed through a plug of Celite® and concentrated under reduced pressure to afford crude aldehyde 451 as a colourless oil. The crude product was then purified by column chromatography (silica gel, hexanes:EtOAc, 70:30 → 40:60) to afford 451 as a colourless oil (92%, 98 mg).

Method I – DMP oxidation.

To alcohol 450 (219 mg, 1.0 mmol, 1.0 eq.) in CH₂Cl₂ (10.0 mL) was added freshly prepared DMP (1272 mg, 3.0 mmol, 3.0 eq.). The reaction was stirred for 1 h or until complete consumption of starting alcohol as indicated by TLC. The reaction was then quenched by the addition of a solution of sat. aq. NaHCO₃ (5 mL), a solution of sat. aq. Na₂S₂O₃ (5 mL) and then diluted with CH₂Cl₂ (10 mL). The layers were separated and the aqueous phase was washed with CH₂Cl₂ (3 × 10 mL). The combined organic layers were then washed with solutions of sat. NaHCO₃ (10 mL) and sat. Na₂S₂O₃ (10 mL). The combined organic layers were then washed with brine, dried over MgSO₄ and concentrated under reduced pressure to afford crude aldehyde 451 as a yellow oil. The crude product was then purified by column chromatography (silica gel, hexanes:EtOAc, 70:30 → 40:60) to afford 451 as a colourless oil (94%, 203 mg).

Method J – Swern oxidation.

To oxalyl chloride (4478 μL, 52.226 mmol, 1.83 eq.) in CH₂Cl₂ (142.0 mL) at -78 °C was added DMSO (9450 μL, 133.28 mmol, 4.67 eq.) in CH₂Cl₂ (42.80 mL) over 10 min. This solution was stirred for a further 5 min and then alcohol 450 (6250 mg, 28.54 mmol, 1.0 eq.) in CH₂Cl₂ (42.0 mL) and DMSO (9.45 mL) was added dropwise over 10 min maintaining the temperature at -78 °C. This mixture was then stirred for 1 h followed by the addition of NEt₃ (23780 μL, 833 μL/mmol alcohol). The reaction was then allowed warm to rt over 1 h. After reaching room temperature the reaction was quenched by the addition of brine (50 mL). The
layers were separated and the aqueous phase washed with CH$_2$Cl$_2$ (3 × 10 mL). The combined organic layers were then washed with brine (20 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the crude aldehyde 451 as a colourless oil. The crude product was then purified by column chromatography (silica gel, hexanes:EtOAc, 70:30 → 40:60) to afford 451 as a colourless oil (84%, 5197 mg).

4-(1,3-Dioxoisindolin-2-yl)butanal (451)

Following Method H to alcohol 450 (1000 mg, 4.566 mmol, 1.0 eq.) in MeCN (45.0 mL) was added freshly prepared IBX (3835 mg, 13.69 mmol, 3.0 eq.). The mixture was heated to 50°C for 1.5 h and then worked up according to Method H.

Yield: 96% (4998 mg)

Physical State: Colourless oil

Method K – SnCl\(_4\) reduction.

To nitro 452 (278 mg, 1.0 mmol, 1.0 eq.) in EtOAc (7.3 mL, degassed) was added SnCl\(_2\).2H\(_2\)O (1800 mg, 8.0 mmol, 8.0 eq.) at rt. The reaction mixture was heated to 80 °C with a reflux condenser attached. The reaction was stirred for 4.5 h after which time it was cooled to rt and diluted with EtOAc (10 mL). The solution was then filtered through a pad of Celite© and concentrated under reduced pressure. The resulting product was then used without further purification.

Method L – Zinc reduction

To nitro 452 (278 mg, 1.0 mmol, 1.0 eq.) in EtOH (3.0 mL) was added H\(_2\)O (1.0 mL) at rt. To this mixture was added Zn powder (325 mg, 5.0 mmol, 5.0 eq.) in one portion. Conc. HCl (1.10 ml, 12 M) was added dropwise to this vigorously stirred solution. The reaction was left to stir at rt for 5 h after which time the reaction was deemed complete by the full consumption of starting nitro 452 as indicated by TLC analysis. The reaction mixture was diluted with EtOAc and filtered through a double thickness of filter paper to remove the Zn residues. The mixture was concentrated under reduced pressure to afford the crude product. The resulting product was then used without further purification.
Method M – H₂, Pd/C reduction

To nitro 452 (278 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd/C (10 wt-%, 150 mg). The flask was then hydrogenated (3 atm.) over a period of 7 h. The flask was flushed with argon, the solution diluted with EtOH (5 mL) and then filtered through a double thickness of filter paper. The product was concentrated under reduced pressure. The solution was then filtered through a pad of Celite® and concentrated under reduced pressure. The resulting product was then used without further purification.

2-(5-Nitro-4-oxopentyl)isoindoline-1,3-dione (454)

To alcohol 452 (500 mg, 1.798 mmol, 1.0 eq.) in CH₂Cl₂ (9.0 mL) was added freshly prepared DMP (2287 mg, 3.0 mmol, 3.0 eq.). The reaction was stirred for 1 h or until complete consumption of starting alcohol as indicated by TLC. The reaction was then quenched by the addition of a solution of sat. aq. NaHCO₃ (5 mL), a solution of sat. aq. Na₂S₂O₃ (5 mL) and then diluted with CH₂Cl₂ (10 mL). The layers were separated and the aqueous phase was washed with CH₂Cl₂ (3 × 10 mL). The combined organic layers were then washed with solutions of sat. aq. NaHCO₃ (10 mL) and sat. aq. Na₂S₂O₃ (10 mL). The combined organic layers were then washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced pressure to afford crude ketone 454 as a white solid. The product was the recrystallized from CH₂Cl₂/EtOAc (90:10, 15 mL) to afford the desired compound.

Yield: 87% (433 mg).

Physical State: White, free flowing powder.

Mp: 128-131 °C.

Method K – SnCl$_4$ reduction.

To nitro 454 (276 mg, 1.0 mmol, 1.0 eq.) in EtOAc (5.0 mL, degassed) was added SnCl$_2$.H$_2$O (1800 mg, 8.0 mmol, 8.0 eq.) at rt. The reaction mixture was heated to 80 °C with a reflux condenser attached. The reaction was stirred for 4.5 h after which time it was cooled to rt and diluted with EtOAc (10 mL). The solution was then filtered through a pad of...
Celite© and concentrated under reduced pressure. The resultant mixture was then dissolved in CH$_2$Cl$_2$ (~2 mL) and then HCl (4 M in Et$_2$O) was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et$_2$O (5 mL) to afford the desired product 455 (43%, 121 mg).

**Method L – Zinc reduction**

To nitro 454 (276 mg, 1.0 mmol, 1 eq.) in EtOH (5.0 mL) was added H$_2$O (0.8 mL) at rt. To this mixture was added Zn powder (325 mg, 5.0 mmol, 5.0 eq.) in one portion. Conc. HCl (0.8 ml, 12 M) was added dropwise to this vigorously stirred solution. The reaction was left to stir at rt for 5 h after which time the reaction was deemed complete by the full consumption of starting nitro 454 as indicated by TLC analysis. The reaction mixture was diluted with EtOAc and filtered through a double thickness of filter paper to remove the Zn residues. The mixture was concentrated under reduced pressure to afford the crude product. Et$_2$O (10 mL) was added and the resulting solid triturated. The solid was filtered, washed with a further Et$_2$O (10 mL) and collected to yield the desired amine as the hydrochloride salt 455 (47%, 132 mg).

**Method M – H$_2$, Pd/C reduction**

To nitro 454 (276 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd / C (10 wt- %, 150 mg). The flask was then hydrogenated (1 atm.) over a period of 7 h. The flask was flushed with argon, the solution diluted with EtOH (5 mL) and then filtered through a double thickness of filter paper. The product was concentrated under reduced pressure. The solution was then filtered through a pad of Celite© and concentrated under reduced pressure. The resultant mixture was then dissolved in CH$_2$Cl$_2$ (~2 mL) and then HCl (4 M in Et$_2$O) was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et$_2$O (5 mL) to afford the desired product 455 (74%, 208 mg).
Chapter 8  Experimental procedures and data

Method O – H₂, Pd/C reduction (3 atm.)

To nitro 454 (276 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd / C (10 wt- %, 150 mg). The flask was then hydrogenated (3 atm.) over a period of 7 h. The flask was flushed with argon, the solution diluted with EtOH (5 mL) and then filtered through a double thickness of filter paper. The product was concentrated under reduced pressure. The solution was then filtered through a pad of Celite® and concentrated under reduced pressure. The resultant mixture was then dissolved in CH₂Cl₂ (~2 mL) and then HCl (4 M in Et₂O) was added dropwise until the desired amine crashed out as the HCl salt. This was then filtered and washed with Et₂O (5 mL) to afford the desired product 455 (85%, 239 mg).

2-(5-Amino-4-oxopentyl)isoindoline-1,3-dione (455)

Following Method O to nitro 454 (276 mg, 1.0 mmol, 1.0 eq.) in MeOH (3.0 mL) was added Pd / C (10 wt- %, 150 mg). The flask was then hydrogenated (3 atm.) over a period of 12 h. The reaction was then worked up according to Method O.

Yield: 85% (239 mg).

Physical State: Grey salt.

Mp: 146-149 °C.

Rf: Baseline (EtOAc).

IR νmax (film)/cm⁻¹: 3018 (NH), 2966, 1769, 1703, 1557, 1402, 1233, 1055, 722.

Guanidylation of Compounds 453 and 455.

Method N - General method for guanidylation.

To amine 453 or 455 (1.0 mmol, 1.0 eq.) in solvent (5.0 mL) was added NEt₃ (152 μL, 1.1 mmol, 1.1 eq.) followed by thiourea guanidylating agent (1.2 mmol, 1.2 eq.). The mixture was then cooled to 0 °C and the Lewis acid promoter (1.1 mmol, 1.1 eq.) was added in one portion. The reaction was then stirred for 10 h at the said temperature or until the starting amine was fully consumed as indicated by TLC analysis. At this point the reaction was diluted with EtOAc (20 mL) and then filtered through a plug of Celite©. The organic layer was then washed with H₂O (20 mL). The layers were separated and the aqueous phase extracted with EtOAc (3 × 30 mL). The combined organic phases were then washed with brine (20 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the crude product which was purified by column chromatography (silica gel, hexanes:EtOAc, 90:10 → 40:60) to afford the desired product.
Guanidylation of Compounds 453 and 455.

δ 1.45 (s, 9H, $t$-Bu), 1.47 (s, 9H, $t$-Bu), 1.98 (app. quin., 2H, H-6), 2.47 (t, $J = 7.2$ Hz, 2H, H-7), 3.69 (t, $J = 7.2$ Hz, 2H, H-5), 4.29 (app. d, 2H, H-8), 7.66 - 7.71 (m, 2H, H-2,3), 7.79 - 7.82 (m, 2H, H-1,4), 8.99 (br s, NH), 11.36 (br s, NH).

**$^{13}$C NMR (100 MHz, CDCl$_3$):**
δ 22.6 (CH$_2$), 28.1 (3CH$_3$), 28.4 (3CH$_3$), 37.0 (CH$_2$), 50.9 (CH$_2$), 79.6 (CH$_2$), 83.6 (2qC), 123.4 (2CH), 132.1 (2qC), 134.1 (2CH), 152.9 (qC), 155.9 (qC), 163.3 (qC), 168.6 (2qC), 203.2 (CO).

**HRMS ($m/z$ ESI$^+$):**
Found 489.2350 (M$^+$ + H. C$_{24}$H$_{33}$N$_4$O$_7$ Requires 489.2349).
2-[5-(N,N'-di-tert-butoxycarbonyl)guanidino-4-hydroxypentyl]isoindoline-1,3-dione (457)

Following Method N to amine 453 (193 mg, 0.78 mmol, 1.0 eq.) in CH₂Cl₂ (5.0 mL) was added NEt₃ (433 μL, 3.12 mmol, 4.0 eq.) followed by N,N'-Bis-Boc-thiourea (236 mg, 0.856 mmol, 1.1 eq.). The mixture was then cooled to 0 °C and HgCl₂ (232 mg, 0.856 mmol, 1.1 eq.) was added in one portion. The reaction was then stirred for 10 h and then worked up according to Method N.

**Yield:** 34% (130 mg).

**Physical State:** Pale yellow foam.

**Mp:**

**R₁:** 0.22 (EtOAc)

**IR ν_max (film)/cm⁻¹:** 3460, 3025, 2948, 1752, 1726, 1635, 1476, 1385, 1221, 1103, 746.

**¹H NMR (400 MHz, CDCl₃):**

δ 1.46 (s, 9H, t-Bu), 1.49 (s, 9H, t-Bu), 1.64 – 1.93 (m, 4H, H-6,7), 3.25 – 3.41 (m, 2H, H-5), 3.49 – 3.56 (m, 1H, H-8), 3.78 – 3.88 (m, 2H, H-9,9'), 5.04 (br s, OH), 7.50 – 7.60 (m, 3H, H-2,3,4), 7.81 (d, J = 7.2 Hz, 1H, H-1), 8.68 (br s, NH), 11.43 (br s, NH).

**HRMS (m/z ESI⁺):**
1-tert-Butoxycarbonyl-2-tert-butoxycarbonylimino-6-(trichloroacetyl)-1,3,6-triazaspiro[4,4]nonane (462)

To guanidine 456 (30 mg, 0.06 mmol, 1.0 eq.) in an RBF at 0 °C was added N₂H₄ (1M in THF, 70 μL, 0.0737 mmol, 1.2 eq.) in strictly anhydrous conditions under Ar. The reaction was allowed warm to rt over 1 h and then left to stir for 3 h. Once the starting material was fully consumed and imine 461 was present according to TLC, trichloroacetyl chloride (0.18 mmol, 3.0 eq.) and NEt₃ (0.18 mmol, 3.0 eq.) were added at 0 °C. The reaction was stirred at 0 °C for 1 h and then stirred at rt for a further 3 h. To this was added H₂O (1 mL) and CH₂Cl₂/MeOH (90:10, 3 mL). The layers were separated and the aqueous phase further extracted with CH₂Cl₂/MeOH (90:10, 3 x 3 mL). The combined organic layers were concentrated under reduced pressure and purified using Prep. TLC (EtOAc) to afford the desired compound.

Yield: 54% (15 mg).

Physical State: Yellow gel.

Mp: -

Rf: 0.12 (EtOAc).

IR νmax (film)/cm⁻¹: 1810, 1725, 1645, 1452, 1300, 1101, 990.

¹H NMR (600 MHz, CDCl₃): δ 1.48 (s, 9H, t-Bu), 1.51 (s, 9H, t-Bu), 1.87 (app. quin., 2H, H-2), 2.05 - 2.10 (m, 1H, H-1), 2.56 - 2.57 (m, 1H, H-1'), 3.83 - 3.87 (m, 1H, H-3), 4.29 (app. t, 1H, H-3'), 3.44 (app. t, 1H, H-4'), 3.98 - 3.99 (m, 1H, H-4), 9.65 (br s, NH)

¹³C NMR (151 MHz, CDCl₃): δ 22.9 (CH₂), 27.2 (3CH₃), 28.4 (3CH₃), 37.4 (CH₂), 49.8 (CH₂), 65.6 (CH₂), 81.1 (qC), 84.2 (qC), 85.2 (qC), 93.7 (qCCl₃), 146.3 (qC), 153.2 (qC), 158.0 (qC), 172.2 (qCO).

HRMS (m/z ESI⁺): Found 485.1113 (M⁺ + H. C₁₈H₂₈Cl₃N₄O₅ Requires 485.1120).
8.4. Investigations into the synthesis of araiosamines A-D.

General Procedures for experiments conducted in the Baran laboratories.

All reactions were carried out under an argon atmosphere with dry solvents using anhydrous conditions unless otherwise stated. Dry diethyl ether (Et₂O), dichloromethane (CH₂Cl₂), acetonitrile (CH₃CN), toluene (PhMe), tetrahydrofuran (THF), methanol (MeOH), and triethylamine (Et₃N) were obtained by passing these previously degassed solvents through activated alumina columns. Reagents were purchased at the highest commercial quality and used without further purification, unless otherwise stated. Yields refer to chromatographically and spectroscopically (¹H NMR) homogeneous materials, unless otherwise stated. Reactions were monitored by thin layer chromatography (TLC) carried out on 0.25 mm E. Merck silica gel plates (60F-254) using UV light as the visualizing agent and an acidic mixture of anisaldehyde, phosphomolybdic acid, or ceric ammonium molybdate, or basic aqueous potassium permanganate (KMnO₄), and heat as developing agents. E. Merck silica gel (60, particle size 0.0430–0.063 mm) was used for flash column chromatography. Preparative thin layer chromatography (PTLC) separations were carried out on 0.25 or 0.50 mm E. Merck silica gel plates (60F-254). Concentration of organic solvents was performed on a rotary evaporator under reduced pressure followed by further evacuation using a two-stage mechanical pump. NMR spectra were recorded on Bruker DRX-600, DRX-500 and AMX-400 instruments and calibrated using residual undeuterated solvent as an internal reference (CHCl₃ @ δ 7.26 ppm ¹H NMR, δ 77.16 ¹³C NMR; CH₂Cl₂ @ δ 53.22 ppm ¹H NMR, δ 353.84 ppm ¹³C NMR). The following abbreviations (or combinations thereof) were used to explain ¹H NMR multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, quin. = quintet, m = multiplet, br = broad. High-resolution mass spectra (HRMS) were recorded on Agilent LC/MSD TOF mass spectrometer by electrospray ionization time of flight reflectron experiments. Melting points were recorded on a Fisher-Johns 12-144 melting point apparatus and are uncorrected.

Characterisation of the following compounds was deemed sufficiently thorough by Prof. Baran due to the short time frame of this project in the Scripps Research Institute, USA.
4-(1H-Indol-3-yl)imidazolidin-2-imine hydrochloride (468)

To azide 484 (500 mg, 1.66 mmol, 1.0 eq.) in THF (20.0 mL) was added PPh₃ (870.4 mg, 3.32 mmol, 2.0 eq.), H₂O (1.0 mL) and the mixture heated to 60 °C for 1 h. The solution was allowed cool to rt and EtOAc (20 mL) was added. This solution was then washed with 4 M HCl (10 mL) which deprotected the Boc group and protonated both amines. The acidified aqueous phase was then subsequently washed with CH₂Cl₂/MeOH (80:20, 2 × 10 mL) and the aqueous phase then concentrated under reduced pressure to afford the desired crude diamine 485 (262 mg, 64% crude).

To the crude diamine 485 (230 mg, 0.93 mmol, 1.0 eq.) in EtOH (4.0 mL) was added NaOAc (152 mg, 1.86 mmol, 2.0 eq.) at rt. To this was added dropwise cyanogen bromide (3 M in CH₂Cl₂, 0.46 mL, 1.39 mmol, 1.5 eq.) and allowed to stir until deemed complete (TLC, 4 h). NaOH (1M solution, 10 mL) was added to the solution and the product extracted with IPA/Chloroform (20:80, 3 × 20 mL). The organic layer was then washed with 2 M HCl (25 mL). The aqueous layer was now washed a further time with EtOAc (3 × 20 mL). The aqueous layer was then concentrated under reduced pressure to yield crude product 468. This crude oil was dissolved in the minimum amount of H₂O (~0.5 mL) and passed through a plug of reverse phase silica (C₈) to yield the desired guanidine.

Yield: 55% (120 mg).

Physical State: Yellow viscous oil.

Mp: -

Rf: Baseline (EtOAc).
**Experimental procedures and data**

**1H NMR (400 MHz, D₂O):**

δ 3.74 (dd, J = 7.2, 2.8 Hz, 1H, H-9), 4.09 (t, J = 7.2 Hz, 1H, H-8), 5.43 (dd, J = 7.2, 2.8 Hz, 1H, H-9'), 7.24 (app. t, 1H, H-6), 7.35 (app. t, 1H, H-5), 7.44 (s, 1H, H-2), 7.61 (d, J = 8.0 Hz, 1H, H-7), 7.68 (d, J = 8.0 Hz, 1H, H-4).

**HRMS (m/z ESI⁺):** Found 201.1136 (M⁺ + H. C₁₁H₁₃N₄ Requires 201.1135).

Attempted trimerization reaction conditions of 468.

To guanidine 468 (20 mg, 0.1 mmol, 1.0 eq.) in D₂O (0.1 mL) was added acid (TFA or 6 M HCl, 0.5 mmol, 5.0 eq.). This mixture was heated (rt, 40 °C or 80 °C) and was monitored by taking aliquots for 1H NMR spectroscopy.
2-tert-Butoxycarbonylamino-1-methyl-1,5-dihydro-4H-imidazol-4-one (477)

\[
\begin{align*}
\text{NHBoc} \\
\text{O}
\end{align*}
\]

To creatinine (1130 mg, 10.0 mmol, 1.0 eq.) in THF (50.0 mL) was added NaH (400 mg, 60% in mineral oil, 10.0 mmol, 1.0 eq.). This was followed by the addition of Boc\(_2\)O (2398 mg, 11.0 mmol, 1.1 eq.) in one portion. The reaction was stirred at room temperature for 12 h and subsequently quenched by the addition of water (10 mL). The resulting solution was extracted with IPA/Chloroform (80:20, 3 x 75 mL). The combined organic layers were then dried with MgSO\(_4\), and concentrated to roughly 10 mL under reduced pressure. Hexanes (20 mL) were added until a white solid crashed out. This solid was filtered off and washed with cold hexanes (10 mL) to yield the title compound.

Spectral data for this compound were consistent with those in the literature.\(^{276}\)

**Yield:** 38\% (800 mg).

**Physical State:** White solid.

**Mp:** 35–36 °C (Lit. 33-34 °C).

**R\_f:** 0.86 (hexanes:EtOAc, 70:30).

**\(^1\)H NMR (400 MHz, CDCl\(_3\)):** δ 1.51 (s, 9H, t-Bu), 3.10 (s, 3H, H-2), 3.90 (s, 2H, H-1), 10.45 (br s, NH).
2-tert-Butyloxycarbonylamino(5,5-di(1H-indol-3-yl)-1-methyl-4,5-dihydro-1H-imidazol-4-one (479)

To a solution of Boc- creatinine 477 (79 mg, 0.37 mmol, 1.0 eq.) and indole 478 (86 mg, 0.742 mmol, 2.0 eq.) in THF (0.370 mL) at -78 °C was added LiHMDS (1 M in THF, 1.224 mmol, 3.3 eq.). This solution was allowed to stir for 30 min. To this was added copper (II) 2-ethylhexanoate (194 mg, 0.556 mmol, 1.5 eq.) by quickly removing the septa and adding the solid. The reaction was allowed warm to rt over 2 h. EtOAc (5 mL) and water (3 mL) were added to the reaction mixture. The aqueous phase was further extracted with EtOAc (3 × 5 mL). The combined organic layers were washed with 0.5 M HCl (5 mL), brine (5 mL), dried over MgSO₄ and then concentrated under reduced pressure to afford the crude product. This was then purified by preparative TLC (hexanes:EtOAc, 50:50) to yield the title compound.

Yield: 25% (40 mg).

Physical State: Yellow gel.

Mp:

Rf: 0.48 (hexanes:EtOAc, 50:50).

¹H NMR (400 MHz, CDCl₃): δ1.59 (s, 9H, t-Bu), 2.89 (s, 3H, H-8), 7.09 (app. t, 2H, H-6,6'), 7.26 (app. t, 2H, H-5,5'), 7.36-7.38 (m, 4H, H-2,2',7,7'), 7.57 (d, J = 8.0 Hz, 2H, H-4,4'), 11.38 (br s, NH Boc), 11.48 (br s, 2NH).
Chapter 8

Experimental procedures and data

*N-tert*-Butoxycarbonyltryptamine (483)

\[
\text{NHBOc}
\]

To tryptamine HCl (3920 mg, 20.0 mmol, 1.0 eq.) in 1,4-dioxane (20.0 mL) was added NEt\textsubscript{3} (8.30 mL, 60.0 mmol, 3.0 eq.) at 0 °C. To this was added Boc\textsubscript{2}O (5235 mg, 24.0 mmol, 1.2 eq.) in 1,4-dioxane (10.0 mL). The solution was left to stir for 1.5 h upon which time the reaction was deemed complete (TLC). The solution was concentrated under reduced pressure and purified by column chromatography (silica gel, hexanes:Et\textsubscript{2}O, 66:34) to afford the desired product.

Spectral data for this compound were consistent with those in the literature.\textsuperscript{277}

**Yield:** 96% (5012 mg).

**Physical State:** Colourless oil.

**Mp:** -

**R\textsubscript{r}:** 0.56 (hexanes:EtOAc, 60:40).

**\textsuperscript{1}H NMR (400 MHz, CDCl\textsubscript{3}):** 81.47 (s, 9H, t-Bu), 2.97 (t, J = 6.2 Hz, 2H, H-8), 3.48 (m, 2H, H-9), 4.68 (br s, NH), 7.02 (s, 1H, H-2), 7.12-7.16 (m, 1H, H-6), 7.22-7.24 (m, 1H, H-5), 7.39 (d, J = 7.9 Hz, 1H, H-7), 7.62 (d, J = 7.9 Hz, 1H, H-4), 8.30 (br s, NH).
2-Azido-tert-butoxycarbonyltriptamine (484)

To compound 483 (1565 mg, 6.0 mmol, 1.0 eq.) in THF (30.0 mL) at 0 °C was added TMSN₃ (1.58 mL, 12.0 mmol, 2.0 eq.). Subsequently 2,3-dichloro-5,6-dicyano-p-benzoquinone (DDQ, 1776 mg, 7.80 mmol, 1.3 eq.) in THF (30.0 mL) was added and allowed to warm to room temperature over 16 h. The reaction now deemed complete (TLC) was diluted with EtOAc (250 mL) and washed repeatedly with a solution of sat. aq. NaHCO₃ (10 × 50 mL) removing a large quantity of the deep red colour from the organic solution. The organic layer was further washed with brine (50 mL), dried with MgSO₄ and concentrated under reduced pressure to afford the crude product as a deep red gel. This was then purified by column chromatography (silica gel, hexanes:Et₂O, 67:33) to afford the title compound as a yellow solid.

Spectral data for this compound were consistent with those in the literature.²⁵²

Yield: 75% (1354 mg).
Physical State: Yellow solid.
Mp: 65-66 °C (Lit. 64-66 °C).
Rᵣ: 0.45 (hexanes:Et₂O, 70:30).
¹H NMR (400 MHz, CDCl₃): δ1.47 (s, 9H, t-Bu), 3.46-3.53 (m, 1H, H-9), 3.62-3.68 (m, 1H, H-9'), 4.94-4.98 (m, 1H, H-8), 7.14-7.18 (m, 2H, H-2,6), 7.24 (app. t, 1H, H-5), 7.40 (d, J = 7.2 Hz, 1H, H-7), 7.72 (d, J = 7.2 Hz, 1H, H-4), 8.54 (br s, NH).
2-tert-Butoxycarbonylamino-5-\((E)-(1H\text{-indol-3-yl})\)methylene]-1-methyl-4,5-dihydro-4\(H\)-imidazol-4-one (489)

To 3-indolecarboxaldehyde 488 (43 mg, 0.30 mmol, 1.2 eq.) and Boc-creatinine 477 (53 mg, 0.25 mmol, 1.0 eq.) in EtOH (0.5 mL) at rt was added piperazine (25 mg, 0.30 mmol, 1.2 eq.). The reaction mixture was then heated to 60 °C upon which the solution turned an intense yellow colour. After 4 h the reaction was deemed complete (TLC). The reaction was diluted with EtOAc (5 mL) and then washed with water (5 mL). The aqueous phase was then further extracted with EtOAc (3 × 5 mL). The combined organic layers were then washed with brine (5 mL), dried over MgSO\(_4\) and concentrated under reduced pressure. The crude product was purified by column chromatography (silica gel, hexanes:EtOAc, 50:50) to yield an intensely yellow solid as the desired product.

**Yield:** 80% (67 mg).

**Physical State:** Bright yellow solid.

**MP:** 174-175 °C.

**Rf:** 0.30 (hexanes:EtOAc, 50:50).

**\(^1\)H NMR (400 MHz, CDCl\(_3\)):** \(\delta\) 1.55 (s, 9H, t-Bu), 3.45 (s, 3H, H-9), 6.81 (s, 1H, H-8), 7.28 – 7.32 (m, 2H, H-5,6), 7.45 (d, \(J = 7.2\) Hz, 1H, H-7), 7.75 (d, \(J = 7.2\) Hz, 1H, H-4), 8.60 (br s, NH) 9.00 (s, 1H, H-2), 10.50 (br s, NHBoc).
Typical condition for functionalisation of 489.

To indole 489 (34 mg, 0.1 mmol, 1.0 eq.) in solvent (0.5 mL) was added the reagent (0.2 mmol, 2.0 eq.). If so required, a further additive (0.2 mmol, 2.0 eq.) was now added. Temperature was set as required. The reaction was monitored by TLC and each showed no progress in the forward direction with unchanged starting materials being isolable at the end of the reaction.

\(^a\) RSM – Recovered starting material.
(E)-N-(2-(1H-indol-3-yl)ethylidene)-4-methylbenzenesulfinamide (500)

To alcohol 504 (242 mg, 1.5 mmol, 1.0 eq.) in MeCN (6.0 mL) was added IBX (1260 mg, 4.5 mmol, 3.0 eq.). The solution was then heated to 80 °C for 3 h. This mixture was then cooled to rt and then filtered through a pad of Celite©. The resulting organic solution was then concentrated to roughly 3 mL and then continued on to the next step.

To crude aldehyde 505 (1.5 mmol, 1.0 eq.) in MeCN (~ 3.0 mL) was added sulfonamide 506 (232 mg, 1.5 mmol, 1 eq.). To this mixture was then added dropwise Ti(Oi-Pr)₄ (898 µL, 3.0 mmol, 2.0 eq.) at rt and allowed to stir for 8 h. The reaction mixture was then evaporated under reduced pressure. The remaining residue was then diluted with hexanes (5 mL) and EtOAc (5 mL) and the solid impurities removed by filtration. The crude product was then purified by preparative TLC (hexanes:EtOAc, 50:50) to yield the desired imine in 12% yield over the two steps.

Yield: 12% (53 mg).

Physical State: Yellow/white solid

Rf: 0.61 (EtOAc).

¹H NMR (400 MHz, CDCl₃): δ 2.42 (s, 3H, H-12), 3.93 (d, J = 5.6 Hz, 2H, H-8), 7.05 – 7.07 (m, 2H, H-2,6), 7.20 (app. t, 1H, H-5), 7.30 (d, J = 8.0 Hz, 2H, H-11,13), 7.36 (d, J = 7.6 Hz, 1H, H-7), 7.45 (d, J = 7.6 Hz, 2H, H-4), 7.55 (d, J = 8.0 Hz, 2H, H-10,14), 8.19 (br s, NH), 9.70 (app. br s, 1H, H-9)

HRMS (m/z ESI⁺): Found 297.1060 (M⁺ + H. C₁₇H₁₇N₂OS Requires 297.1056).
(Z)-N-(2-(1-tosyl-1H-indol-3-yl)vinyl)acetamide (501)

(a) To carboxylic acid 510 (150 mg, 0.38 mmol, 1.0 eq.) in THF (1.5 mL) was added pyridine (0.060 mL, 0.75 mmol, 2.0 eq.) and Cu(OAc)$_2$ (20.4 mg, 0.11 mmol, 0.33 eq.) at 0 °C. An instant blue colour was observed. This mixture was stirred for 5 min followed by addition of Pb(OAc)$_4$ (182.7 mg, 0.41 mmol, 1.1 eq.) which immediately turned the reaction mixture a notable green colour. The reaction was stirred vigorously and allowed warm to rt over 2 h. The reaction was quenched by the addition of a solution of sat. aq. NaHCO$_3$ (3 mL) and the product extracted with EtOAc (3 × 5 mL). The combined organic phases were then washed with brine (5 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the crude product as an off white solid (130 mg, 84%) which was used without further purification.

(b) The crude hemi-aminal 511 (125 mg, 0.30 mmol, 1.0 eq.) was dissolved in THF (1.0 mL) and to this was added LiClO$_4$ (192 mg, 1.81 mmol, 6.0 eq.) at 0 °C. This was stirred for 5 min after which time DIPEA (0.157 mL, 0.90 mmol, 1.0 eq.) was added dropwise. The reaction mixture was stirred for 10 min at 0 °C and then for 30 min (or until starting material was no longer detected, TLC) at rt. The reaction was quenched by the addition of a solution of sat. aq. NaHCO$_3$ (3 mL) and the product extracted with EtOAc (3 × 5 mL). The combined organic phases were then washed with brine (5 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the crude enamide product 501 which was purified by column chromatography (silica gel, hexanes:EtOAc, 90:10 → 60:40, column pretreated with NEt$_3$, 1%). Enamide 501 was obtained in 76% yield over the two steps.

**Yield:** 76% (81 mg).

**Physical State:** Beige waxy solid.

**R$_g$:** 0.58 (hexanes:EtOAc, 20:80 - p-anisaldehyde stain).
**1H NMR (400 MHz, CDCl3):**  
δ 2.08 (s, 3H, H-Ac), 2.35 (s, 3H, H-12), 5.69 (d, J = 9.4 Hz, 1H, H-8), 7.09 (app. t, 1H, H-6), 7.23 - 7.31 (m, 3H, H-9,11), 7.37 (app. t, 1H, H-5), 7.47 (d, J = 8.0 Hz, 1H, H-7), 7.53 (s, 1H, H-2), 7.78 (d, J = 8.0 Hz, 2H, H-10), 8.01 (d, J = 8.4 Hz, 1H, H-4), 8.77 (br s, NH).

**HRMS (m/z ESI):**  
Found 355.1113 (M+ + H. C_{19}H_{19}N_{2}O_{3}S Requires 355.1111).

**2-Hydroxyethylindol (504)**

![2-Hydroxyethylindol (504)](image)

To lithium aluminium hydride (760 mg, 20.0 mmol, 2.0 eq.) in THF (30.0 mL) was added 2-(indol-3-yl)acetic acid 503 (1750 mg, 10.0 mmol, 1.0 eq.) in THF (20.0 mL) at 0 °C. This solution was stirred at 0 °C for 2 h and a further 10 h at rt. The reaction was now determined to be complete (TLC) and therefore quenched by the initial addition of water (1.75 mL), NaOH (10% aqueous solution, 3.5 mL) and then H2O (6 mL). MgSO4 was added and the resulting solids filtered through a pad of Celite©. The resulting mixture was extracted with EtOAc (3 × 50 mL). The combined organic layers were then washed with brine (50 mL), dried over MgSO4 and concentrated under reduced pressure to afford alcohol 504 (1545 mg) which was used without further purification.

Spectral data for this compound were consistent with those in the literature.278

**Yield:** 96% (1545 mg).

**Physical State:** Off white solid.

**Mp:** 54-57 °C (Lit. 54-55 °C)

**Rf:** 0.39 (EtOAc).
**Chapter 8 Experimental procedures and data**

\[ ^1H \text{NMR (400 MHz, CDCl}_3\]:} \[ \delta \, 1.54 \text{ (br s, OH), 3.04 (t, } J = 6.2 \text{ Hz, 2H, H-8), 3.91 (m, 2H, H-9), 7.07 \text{ (s, 1H, H-2), 7.13 (app. t, 1H, H-6), 7.21 (app. t, 1H, H-5), 7.37 (d, } J = 7.6 \text{ Hz, 1H, H-7), 7.63 (d, } J = 7.6 \text{ Hz, 1H, H-4), 8.06 \text{ (br s, NH).}]

(S)-N-Acetyltryptohan methyl ester (508)

To tryptophan methyl ester 507 (7112 mg, 28.0 mmol, 1.0 eq.) in CH\textsubscript{2}Cl\textsubscript{2} (56.0 mL) was added DIPEA (9.45 mL, 56.0 mmol, 2.0 eq.). Subsequently Ac\textsubscript{2}O (2.66 mL, 28.0 mmol, 1.0 eq.) was added dropwise at rt. The reaction was stirred for 1 h. It was then diluted with CH\textsubscript{2}Cl\textsubscript{2} (50 mL), washed with a solution of sat. aq. NaHCO\textsubscript{3} (25 mL), 1 M HCl (25 mL) and then brine (25 mL). The organic phase was dried over MgSO\textsubscript{4}, concentrated under reduced pressure and then purified by column chromatography (silica gel, EtOAc) to afford the desired tryptophan derivative 508.

Spectral data for this compound were consistent with those in the literature.\textsuperscript{279}

**Yield:** 91% (6624 mg).

**Physical State:** White powder.

**Mp:** 150-153 °C (Lit. 152 °C).

**R:**

\[ ^1H \text{NMR (400 MHz, CDCl}_3\]:} \[ \delta \, 1.96 \text{ (s, 3H, H-Ac), 3.33-3.35 \text{ (m, 2H, H-8, 8’), 3.70 \text{ (s, 3H, H-OMe), 4.95-4.96 \text{ (m, 1H, H-9), 6.01 \text{ (br s, NHAc), 6.97 \text{ (s, 1H, H-2), 7.12 \text{ (m, 1H, H-6), 7.20 \text{ (m, 1H, H-5), 7.36 \text{ (d, } J = 8.0 \text{ Hz, 1H, H-7), 7.52 \text{ (d, } J = 8.0 \text{ Hz, 1H, H-4), 8.19 \text{ (br s, NH).}]}\]
To indole 508 (258 mg, 0.98 mmol, 1.0 eq.) in CH$_2$Cl$_2$ (6.0 mL) was added TsCl (562 mg, 2.95 mmol, 3.0 eq.). To this was added NaOH (98 mg, 2.45 mmol, 2.5 eq) and the reaction heated to 35 °C. After 1 h, water (5 mL) was added along with CH$_2$Cl$_2$ (15 mL). The organic layer was washed with water (5 × 5 mL) until the organic layer became nearly clear in appearance. The organic layer was then washed with brine (5 mL), dried over MgSO$_4$ and then concentrated under reduced pressure to afford the crude product. This was then purified by column chromatography (silica gel, hexanes:EtOAc, 60:40 → 0:100) to afford the desired product 509.

Yield: 77% (313 mg).

Physical State: Off beige solid.

Mp: 129-130 °C.

R$_f$: 0.46 (hexanes:EtOAc, 20:80).

$^1$H NMR (400 MHz, CDCl$_3$): δ 2.09 (s. 3H, H-Ac), 2.47 (s, 3H, H-12), 3.32 (dd, 1H, J = 14.8, 16.0 Hz, H-8), 3.40 (dd, J = 14.8, 5.6 Hz, 1H, H-8'), 3.80 (s, 3H, H-OMe), 5.05 (m, 1H, H-9), 6.18 (app. br s, NHAc), 7.35 (d, J = 8.0 Hz, 2H, H-11), 7.38 – 7.45 (m, 3H, H-2,5,6), 7.58 (d, J = 8.0 Hz, 1H, H-7), 7.85 (d, J = 8.0 Hz, 2H, H-10), 8.09 (d, J = 8.0 Hz, 1H, H-4).
Chapter 8

Experimental procedures and data

(S)-N-Acetyl-1-tosyltryptohan (510)

To tryptophan methyl ester derivative 509 (70 mg, 0.169 mmol, 1.0 eq.) in THF (1.0 mL) was added H$_2$O (0.5 mL) at rt. To this mixture was added LiOH (12 mg, 0.289 mmol, 1.7 eq.) in one portion while maintaining vigorous stirring. After 8 h the reaction was diluted with H$_2$O (5 mL) and the pH lowered to 2 using 1 M HCl (~ 15 mL). The product was then extracted from the reaction mixture with EtOAc (3 × 20 mL). The organic layer was then washed with brine (10 mL), dried over MgSO$_4$ and concentrated under reduced pressure to afford the title compound as a colourless gel which was used without further purification.

Yield: 94% (63 mg).

Physical State: Colourless gel.

Mp: -

R$_f$: Baseline (EtOAc).

$^1$H NMR (400 MHz, CDCl$_3$): δ 1.94 (s, 3H, H-Ac), 2.31 (s, 3H, H-12), 3.22 (dd, $J$ = 14.8, 5.4 Hz, 1H, H-8), 3.35 (dd, $J$ = 14.8, 6.0 Hz, 1H, H-8’), 4.91 (m, 1H, H-9), 6.17 (app. br s, NHAc), 7.21 (d, $J$ = 8.0 Hz, 2H, H-11), 7.22 (app. t, 1H, H-6), 7.29 (app. t, 1H, H-5), 7.42 (s, 1H, H-2), 7.48 (d, $J$ = 8.0 Hz, 1H, H-7), 7.71 (d, $J$ = 8.0 Hz, 2H, H-10), 7.98 (d, $J$ = 8.0 Hz, 1H, H-4).
(E)-N-(2-(2-(1-acetamido-2-(1-tosyl-1H-indol-3-yl)ethyl)-1-tosyl-1H-indol-3-yl)vinyl)acetamide (515)

To enamide 501 (30 mg, 0.08 mmol, 1.0 eq.) in CH₂Cl₂ (0.80 mL) at 0 °C was added BF₃·OEt₂ (0.010 mL, 0.08 mmol, 1.0 eq.). The reaction was allowed to stir at 0 °C for 4 h and then at rt for a further 8 h. After this time solutions of sat. NaHCO₃ (2 mL) and sat. Na₂SO₃ (2 mL) were added and the product extracted with CH₂Cl₂ (3 × 10 mL). The combined organic layers were then washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced pressure to afford crude dimeric indole 515. The product was then purified using preparative TLC (EtOAc) to afford the dimeric product.

Yield: 37% (21 mg).

Physical State: Yellow gel.

Mp:

Rf: 0.29 (EtOAc).

Experimental procedures and data

HMBC

314
(Z)-N-((2-(6-nitro-1-tosyl-1H-indol-3-yl)vinyl)acetamide (516)

To tryptophan methyl ester derivative 518 (240 mg, 0.52 mmol, 1.0 eq.) in THF (1.0 mL) was added H₂O (0.5 mL) at rt. To this mixture was added LiOH (12 mg, 0.289 mmol, 1.7 eq.) in one portion while maintaining vigorous stirring. After 8 h the reaction was diluted with H₂O (5 mL) and the pH lowered to 2 using 1 M HCl (~15 mL). The product was then extracted from the reaction mixture with EtOAc (3 × 20 mL). The organic layer was then washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the title compound as a colourless gel which was used without further purification (99%, 230 mg).

(a) To carboxylic acid 519 (196 mg, 0.440 mmol, 1.0 eq.) in THF (4.0 mL) was added pyridine (70 μL, 0.880 mmol, 2.0 eq.) and Cu(OAc)₂ (23 mg, 0.132 mmol, 0.33 eq.) at 0 °C. An instant blue colour was observed. This mixture was stirred for 5 min followed by addition of Pb(OAc)₄ (214 mg, 0.485 mmol, 1.1 eq.) which immediately turned the reaction mixture a notable green-brown colour. The reaction was stirred vigorously and allowed warm to rt over 2 h. The reaction was quenched by the addition of a solution of sat. aq. NaHCO₃ (3 mL) and the product extracted with EtOAc (3 × 5 mL). The combined organic phases were then washed with brine (5 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the crude product as an off white yellow solid which was used without further purification.

(b) The crude product 520 (0.440 mmol, 1.0 eq.) was dissolved in THF (2.0 mL) and to this was added LiClO₄ (279 mg, 2.64 mmol, 6.0 eq.) at 0 °C. This was stirred for 5 min after which time DIPEA (229 μL, 1.32 mmol, 1.0 eq.) was added dropwise. The reaction mixture was stirred for 10 min at 0 °C and then for 30 min (or until starting material was no longer detected, TLC) at rt. The reaction was quenched by the addition of a solution of sat. aq. NaHCO₃ (6 mL) and the product extracted with EtOAc (3 × 10 mL). The combined organic phases were then washed with brine (5 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the crude enamide product 516 which was purified by column
chromatography (silica gel, hexanes:EtOAc, 90:10 → 60:40, column pretreated with NEt₃, 1%). Enamide 516 was obtained in 63% yield over the three steps (110 mg).

**Yield:** 63% (110 mg).

**Physical State:** Yellow gel

**Rf:** Baseline (EtOAc)

**¹H NMR (400 MHz, CDCl₃):** δ 2.10 (s, 3H, H-Ac), 2.38 (s, 3H, H-12), 5.65 (d, J = 9.2 Hz, 1H, H-8), 7.15 (m, 1H, H-9), 7.28 (br s, NH), 7.31 (d, J = 8.0 Hz, 2H, H-11), 7.58 (d, J = 8.0 Hz, 1H, H-4), 7.80 (s, 1H, H-2), 7.84 (d, J = 8.0 Hz, 2H, H-10), 8.16 (dd, J = 8.0, 2.0 Hz, 1H, H-5), 8.88 (d, J = 2.0 Hz, 1H, H-7).

**(S)-N-Acetyl-6-nitro-1-tosyltryptohan methyl ester (518)**

To (S)-N-acetyltryptohan methyl ester 507 (5410 mg, 20.8 mmol, 1.0 eq.) in CH₂Cl₂ (125.0 mL) at 0 °C was added AcOH (6.25 mL, 104.0 mmol, 5.0 eq) followed by HNO₃ (2015 μL, 35.4 mmol, 1.7 eq.) dropwise ensuring to keep the flask well cooled. After the addition the ice bath was removed and the reaction stirred at rt for a further 2 h. After this time, the mixture was cooled to 0 °C and a solution of sat. aq. NaHCO₃ (50 mL) was added. The layers were separated and the aqueous phase extracted with CH₂Cl₂ (3 × 50 mL), the combined organic layers washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced pressure to yield the crude target compound as a mixture of regioisomers. This was then brought forward to the next step without further purification.
To crude nitro 517 (2050 mg, 6.72 mmol, 1.0 eq.) in CH$_2$Cl$_2$ (40.0 mL) was added TsCl (3830 mg, 20.16 mmol, 3.0 eq.) followed by NaOH (537 mg, 13.47 mmol, 2.0 eq.). This mixture was stirred at rt for 3 h after which time the reaction was diluted with water (25 mL) and CH$_2$Cl$_2$ (25 mL). The layers were separated and the aqueous phase extracted with CH$_2$Cl$_2$ (3 × 50 mL), the combined organic layers washed with brine (20 mL), dried over MgSO$_4$ and concentrated under reduced pressure to yield the crude target compound as a mixture of regioisomers. This was then purified by column chromatography (silica gel, hexanes:EtOAc, 60:40 → 0:100) to afford the desired product 518.

Yield: 21% (2004 mg, over 2 steps).

Physical State: Yellow solid.

Rf: 0.64 (EtOAc).

$^1$H NMR (400 MHz, CDCl$_3$): δ 1.99 (s, 3H, H-Ac), 2.37 (s, 3H, H-12), 3.22 (dd, $J = 14.8, 5.0$ Hz, 1H, H-8$'$), 3.33 (dd, $J = 14.8, 6.0$ Hz, 1H, H-8$'$), 3.69 (s, 3H, H-OMe), 4.92 – 4.93 (m, 1H, H-9), 6.03 (br s, NH), 7.29 (d, $J = 8.0$ Hz, 2H, H-11), 7.58 – 7.60 (m, 2H, H-2,7), 7.80 (d, $J = 8.0$ Hz, 2H, H-10), 8.14 (dd, $J = 8.0, 2.0$ Hz, 1H, H-5), 8.85 (d, $J = 2.0$ Hz, 1H, H-4).

2-(1-Allyl-3-indolyl)acetaldehyde (527)

To 2-bromo-N-diallylaniline 530 (618 mg, 2.46 mmol, 1.0 eq.) in dry n-pentane (11.25 mL) and Et$_2$O (1.25 mL) was added t-BuLi (1.5 M in Hexanes, 4.1 mL, 6.16 mmol, 2.5 eq.) at -78 °C. The reaction mixture was stirred at this temperature for 10 min followed by TMEDA (degassed, 927 µL, 6.16 mmol, 2.5 eq.) dropwise. The reaction mixture was further stirred at
-78 °C for 7 min followed by stirring at 0 °C for 40 min. The reaction mixture was then recooled to -78 °C and DMF (2.0 mL) was added dropwise. This was stirred for 10 min after which time the reaction was allowed warm to rt over 1 h. The reaction was then quenched by the addition of a solution of sat. aq. NH₄Cl (4 mL). The organic layer was separated, dried over MgSO₄ and concentrated under reduced pressure to afford the crude aldehyde. This was then purified by column chromatography (hexanes:Et₂O, 80:20) to afford the pure aldehyde.

Spectral data for this compound were consistent with those in the literature.  

**Yield:** 41% (203 mg).

**Physical State:** Colourless oil.

**Mp:** -

**Rf:** 0.39 (hexanes:Et₂O - 80:20).

**¹H NMR (400 MHz, CDCl₃):** δ 2.75 - 3.00 (m, 3H, H-3,8), 3.58 - 3.72 (m, 4H, H-2,10), 5.17 - 5.30 (m, 2H, H-12,13), 5.83 - 5.89 (m, 1H, H-11), 6.51 (d, J = 7.8 Hz, 1H, H-7), 6.65 - 6.69 (m, 1H, H-5), 7.01 - 7.13 (m, 2H, H-4,6), 9.84 (t, J = 1.2 Hz, 1H, H-9).

---

**N-(2-(1-Allylindolin-3-yl)ethylidene)-4-methylbenzenesulfinamide (528)**

![Diagram](image)

To aldehyde 527 (170 mg, 0.85 mmol, 1.0 eq.) and sulfonamide 506 (196 mg, 1.26 mmol, 1.5 eq.) in THF (4.0 mL) was added Ti(Oi-Pr)₄ (500 μL, 1.69 mmol, 2.0 eq.) at rt. This reaction was left to stir at rt for 6 h after which time it was quenched by the addition of brine (2 mL). The mixture was diluted with Et₂O (10 mL) and water (5 mL). The product was extracted with Et₂O (3 × 5 mL). The combined organic layers were washed with brine (10 mL), dried
over MgSO₄ and concentrated under reduced pressure. This crude residue was then purified by column chromatography (hexanes:Et₂O, 80:20) to afford the pure imine 528.

**Yield:** 62% (171 mg).

**Physical State:** Pale yellow oil.

**Mp:** -

**Rₜ:** 0.51 (hexanes:Et₂O - 80:20).

**¹H NMR (400 MHz, CDCl₃):**

**Diallyl-(2-bromophenyl)-amine (530)**

O-Bromoaniline (176 mg, 1.0 mmol, 1.0 eq.) was dissolved in THF (1.0 mL) at -10 °C. To this was added freshly prepared LDA (1.25 M, 800 μL, 1.0 mmol, 1.0 eq.) and allowed to stir for 10 min. To this mixture was then added allyl bromide (87 μL, 1.0 mmol, 1.0 eq.) dropwise and the reaction allowed warm to rt. This solution was stirred for 20 min after which LDA (1.25 M, 800 μL, 1.0 mmol, 1.0 eq.) was added. This mixture was subsequently stirred for a further 10 min then allyl bromide (100 μL, 1.1 mmol, 1.1 eq.) was introduced dropwise. After 1 h the reaction mixture was quenched by the addition of a solution of sat. aq. NH₄Cl (1 mL) and the product extracted with Et₂O (3 x 5 mL). The combined organic layers were washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced
pressure. The crude product was then dissolved in the minimum of hexanes:Et₂O (90:10, 0.5 mL) and passed through a plug of silica eluting with hexanes:Et₂O (90:10).

Spectral data for this compound were consistent with those in the literature.²⁸⁰

Yield: 78% (198 mg).

Physical State: Colourless oil.

Mp: -

Rf: ~0.10 (hexanes:EtOAc, 90:10).

¹H NMR (400 MHz, CDCl₃): δ 3.69 (d, J = 6.0 Hz, 4H, H-7), 5.12 (dd, J = 10.2, 1.6 Hz, 2H, H-10), 5.15 – 5.22 (m, 2H, H-9), 5.82 (ddt, J = 16.4, 10.2, 6.0 Hz, 2H, H-8), 6.89 (app. t, 1H, H-4), 7.04 (dd, J = 8.0, 1.5 Hz, 1H, H-6), 7.22 (app. t, 1H, H-5), 7.56 (dd, J = 8.0, 1.5 Hz, 1H, H-3).

1-tert-Butoxycarbonyl-3-(2-methoxy-2-oxoethyl)-1H-indole (533a)

To a solution of 3-indole acetic acid methyl ester (1060 mg, 5.60 mmol 1.0 eq.) in acetonitrile (4.5 mL) was added DMAP (134 mg, 1.10 mmol 0.2 eq.) and di-tert-butyl dicarbonate (1830 mg, 8.40 mmol, 1.5 eq.) under an inert atmosphere at rt. The resulting reaction mixture was stirred for 8 h at rt. The reaction mixture was diluted with EtOAc (20 mL). Water (5 mL) was added to the reaction mixture. The organic layer was separated; the aqueous layer was extracted with EtOAc (2 × 10 mL). The combined extracts were washed with water (2 × 10 mL), brine (25 mL) and dried over MgSO₄. Solvent was filtered and evaporated under reduced pressure. The crude residue was purified by column chromatography (silica gel, hexanes:EtOAC, 90:10) to afford 533a.

Spectral data for this compound were consistent with those in the literature.²⁸¹
Yield: 86% (1400 mg).

Physical State: Yellow oil.

Mp: -

Rf: 0.53 (hexanes:EtOAc, 95:5).

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 1.66 (s, 9H, $t$-Bu), 3.71 (s, 3H, H-OMe), 3.72 (s, 2H, H-8), 7.26 (app. t, 1H, H-5), 7.33 (app. t, 1H, H-6), 7.52 (d, $J$ = 8.0 Hz, 1H, H-7), 7.57 (d, $J$ = 8.0 Hz, 1H, H-4), 8.22 (s, 1H, H-2).

Benzyl (Z)-(4-(tri-isopropylsilyl)but-1-en-3-yn-1-yl)carbamate (545)

To (E)-5-(triisopropylsilyl)pent-2-en-4-ynoic acid 550 (40 mg, 0.158 mmol, 1.0 eq.) in toluene (5.0 mL) was added DPPA (136 µL, 0.635 mmol, 4.0 eq.) followed by NEt$_3$ (103 µL, 0.746 mmol, 4.7 eq.). The resulting mixture was stirred at rt after which time the reaction diluted with water (5 mL) and EtOAc (15 mL). The organic layer was separated; the aqueous layer was extracted with EtOAc (3 x 10 mL). The combined extracts were washed with brine (25 mL) and dried over MgSO$_4$. The solvent was evaporated under reduced pressure. The crude residue was purified by passing through a plug of silica, eluting with (hexanes:EtOAC, 90:10) and brought onto the next step without characterisation.

To the prepared azide (0.158 mmol, 1.0 eq.) in toluene (5 mL) was added BnOH (328 µL, 3.174 mmol, 20.0 eq.) and the resulting mixture heated to 90 °C for 4 h. The reaction was allowed to cool to rt and then concentrated under reduced pressure. The residue was dissolved in MeOH (2 mL) and K$_2$CO$_3$ (20 mg) added. This mixture was allowed stir at rt for 1 h after which time the reaction was diluted with water (5 mL) and EtOAc (10 mL). The organic layer was separated; the aqueous layer was extracted with EtOAc (3 x 10 mL). The
combined extracts were washed with brine (20 mL) and dried over MgSO₄. The solvent was evaporated under reduced pressure. The crude product was then purified by column chromatography (silica gel, hexanes:EtOAc, 90:10) to afford the title compound.

Yield: 50% (28 mg).

Physical State: Cloudy gel.

Rf: 0.69 (hexanes:EtOAc, 90:10)

¹H NMR (400 MHz, CDCl₃): δ 1.07 – 1.09 (m, 21H, H-TIPS), 4.81 (d, J = 8.0 Hz, 1H, H-1), 5.20 (s, 2H, H-3), 6.96 – 7.01 (m, 1H, H-2), 7.14 (br s, NH), 7.32 – 7.41 (m, 5H, H-4,5,6).

3-(Tri-iso-propylsilyl)prop-2-yn-1-ol (547)

To propargylic alcohol 546 (576 µL, 10.0 mmol, 1.0 eq.) in THF (20.0 mL) at rt was added MeMgBr (1.4 M in Et₂O, 15700 µL, 22.0 mmol, 2.2 eq.) dropwise. The resulting mixture was refluxed for 12 h and then cooled to rt. To this was added TIPS-Cl (1987 µL, 11.0 mmol, 1.1 eq.) and the reaction mixture was refluxed for a further 6 h. After this time period the mixture was cooled to rt and quenched by the addition of a solution of sat. aq. NH₄Cl (15 mL). The mixture was diluted with Et₂O (30 mL) and the layers separated. The organic layer was separated; the aqueous layer was extracted with Et₂O (2 × 15 mL). The combined extracts were washed with brine (25 mL) and dried over MgSO₄. Solvent was filtered and evaporated under reduced pressure. The crude residue was purified by column chromatography (silica gel, hexanes:EtOAC, 90:10) to afford 547.

Spectral data for this compound were consistent with those in the literature.²⁸²

Yield: 53% (1123 mg).
Physical State: Colourless oil.

Mp: -

Rf: 0.83 (Hexanes : EtOAc - 95:5).

^1H NMR (400 MHz, CDCl₃): δ 1.03 – 1.05 (m, 21H, H-TIPS), 4.27 (s, 2H, H-1).

3-(tri-iso-propylsilyl)propionaldehyde (548)

To alcohol 547 (1123 mg, 5.29 mmol, 1.0 eq.) in MeCN (6.5 mL) was added IBX (1779 mg, 6.3 mmol, 3.0 eq.). The solution was then heated to 80 °C for 2 h. This mixture was then cooled to rt, diluted with MeCN (10 mL) and then filtered through a pad of Celite©. The resulting organic solution was then concentrated under reduced pressure. The crude residue was purified by column chromatography (silica gel, hexanes:EtOAC, 90:10) to afford 548.

Spectral data for this compound were consistent with those in the literature.¹²⁸³

Yield: 91% (1010 mg).

Physical State: Colourless oil.

Rf: 0.72 (hexanes:EtOAc, 90:10)

^1H NMR (400 MHz, CDCl₃): δ 1.07 – 1.09 (m, 21H, H-TIPS), 9.18 (s, 1H, H-1).
Ethyl (E)-5-(tri-iso-propylsilyl)pent-2-en-4-ynoate (549)

To LiCl (245 mg, 5.85 mmol, 1.2 eq.) in an RBF was added aldehyde 548 (1024 mg, 4.87 mmol, 1.0 eq.) in MeCN (50.0 mL) at rt. To this was added the triethylphosphonoacetate (1159 μL, 5.85 mmol 1.2 eq.) dropwise followed by DBU (728 μL 4.87 mmol, 1.0 eq.). The resulting mixture was stirred at rt for 10 h after which time the reaction was deemed complete by TLC analysis. The reaction was quenched by the addition of a solution of sat. aq. NH₄Cl (10 mL) and diluted with EtOAc (20 mL). The organic layer was separated; the aqueous layer was extracted with EtOAc (3 × 20 mL). The combined extracts were washed with brine (25 mL) and dried over MgSO₄. Solvent was evaporated under reduced pressure. The crude residue was purified by column chromatography (silica gel, hexanes:EtOAC, 90:10) to afford 549.

Spectral data for this compound were consistent with those in the literature.

Yield: 64% (851 mg)

Physical State: Colourless viscous oil.

Mp: -

Rf: 0.53 (hexanes:EtOAc, 90:10).

¹H NMR (400 MHz, CDCl₃): \( \delta \) 1.07 – 1.08 (m, 21H, H-TIPS), 1.29 (t, \( J = 7.2 \) Hz, 3H, H-1), 4.21 (q, \( J = 7.2 \) Hz, 2H, H-2), 6.26 (d, \( J = 16.0 \) Hz, 1H, H-3), 6.78 (d, \( J = 16.0 \) Hz, 1H, H-4).
(E)-5-(Tri-i50-propylsilyl)pent-2-en-4-ynoic acid (550)

To ester 549 (70 mg, 0.25 mmol, 1.0 eq.) in THF (0.5 mL) was added H₂O (0.25 mL) at rt. To this mixture was added LiOH (30 mg, 0.75 mmol, 3.0 eq.) in one portion while maintaining vigorous stirring. After 8 h the reaction was diluted with H₂O (5 mL) and the pH lowered to 2 using 1 M HCl (∼ 7.5 mL). The product was then extracted from the reaction mixture with EtOAc (3 × 10 mL). The organic layer was then washed with brine (10 mL), dried over MgSO₄ and concentrated under reduced pressure to afford the title compound as a colourless gel which was used without further purification (65%, 41 mg).

Spectral data for this compound were consistent with those in the literature.²⁸⁵

Yield: 65% (41 mg)
Physical State: Colourless gel.
Mp: -
Rf: Baseline (EtOAc).

¹H NMR (400 MHz, CDCl₃): δ 1.05 – 1.08 (m, 21H, H-TIPS), 6.24 (d, J = 16.0 Hz, 1H, H-1), 6.76 (d, J = 16.0 Hz, 1H, H-2).
